The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

“Please don’t cry.”

His mother's depressed. Her sleepless nights are filled with anxieties. She's become irritable and "unloving." He doesn't understand why she has changed.

In anxious depressed patients, Goldberg and Finnerty* found "...patients treated with imipramine pamoate tended ($P<.09$) to have a better quality of sleep than those treated with amitriptyline."

The overall results of the study indicate that both imipramine pamoate and amitriptyline were equally effective in treating neurotic depression.

Before prescribing Tofranil-PM, please review a summary of the full prescribing information on the following page.

Tofranil-PM®
imipramine pamoate

Unsurpassed among tricyclics in treating symptoms of anxious depression

*Goldberg H L, Finnerty R J: Which tricyclic for depressed outpatients, imipramine pamoate or amitriptyline? Dis Nerv Syst *38*: 785-789 (Oct.) 1977.

Geigy

Tofranil-PM®
· imipramine **pamoate**

Geigy

As anxiety, agitation, sleep disturbances, and other depressive symptoms are relieved, mood and motivation may be markedly improved.

Patients are usually alert and capable of functioning at more normal levels of behavior.

Tofranil-PM encourages patient compliance because one capsule lasts from bedtime to bedtime.

Good results are usually seen at the starting dose of one 75-mg capsule h.s.

For many patients, dosage can be safely increased to 150 mg daily.

As with all tricyclics, sedation may occur. Please caution patients against driving or operating dangerous machinery.

Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg of imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

Published by the American Psychiatric Association, Washington, D.C., September 1976. 114 pages. Spiral binding. Single copies, $6.00. For orders of 10 or more, $5.00 per copy.

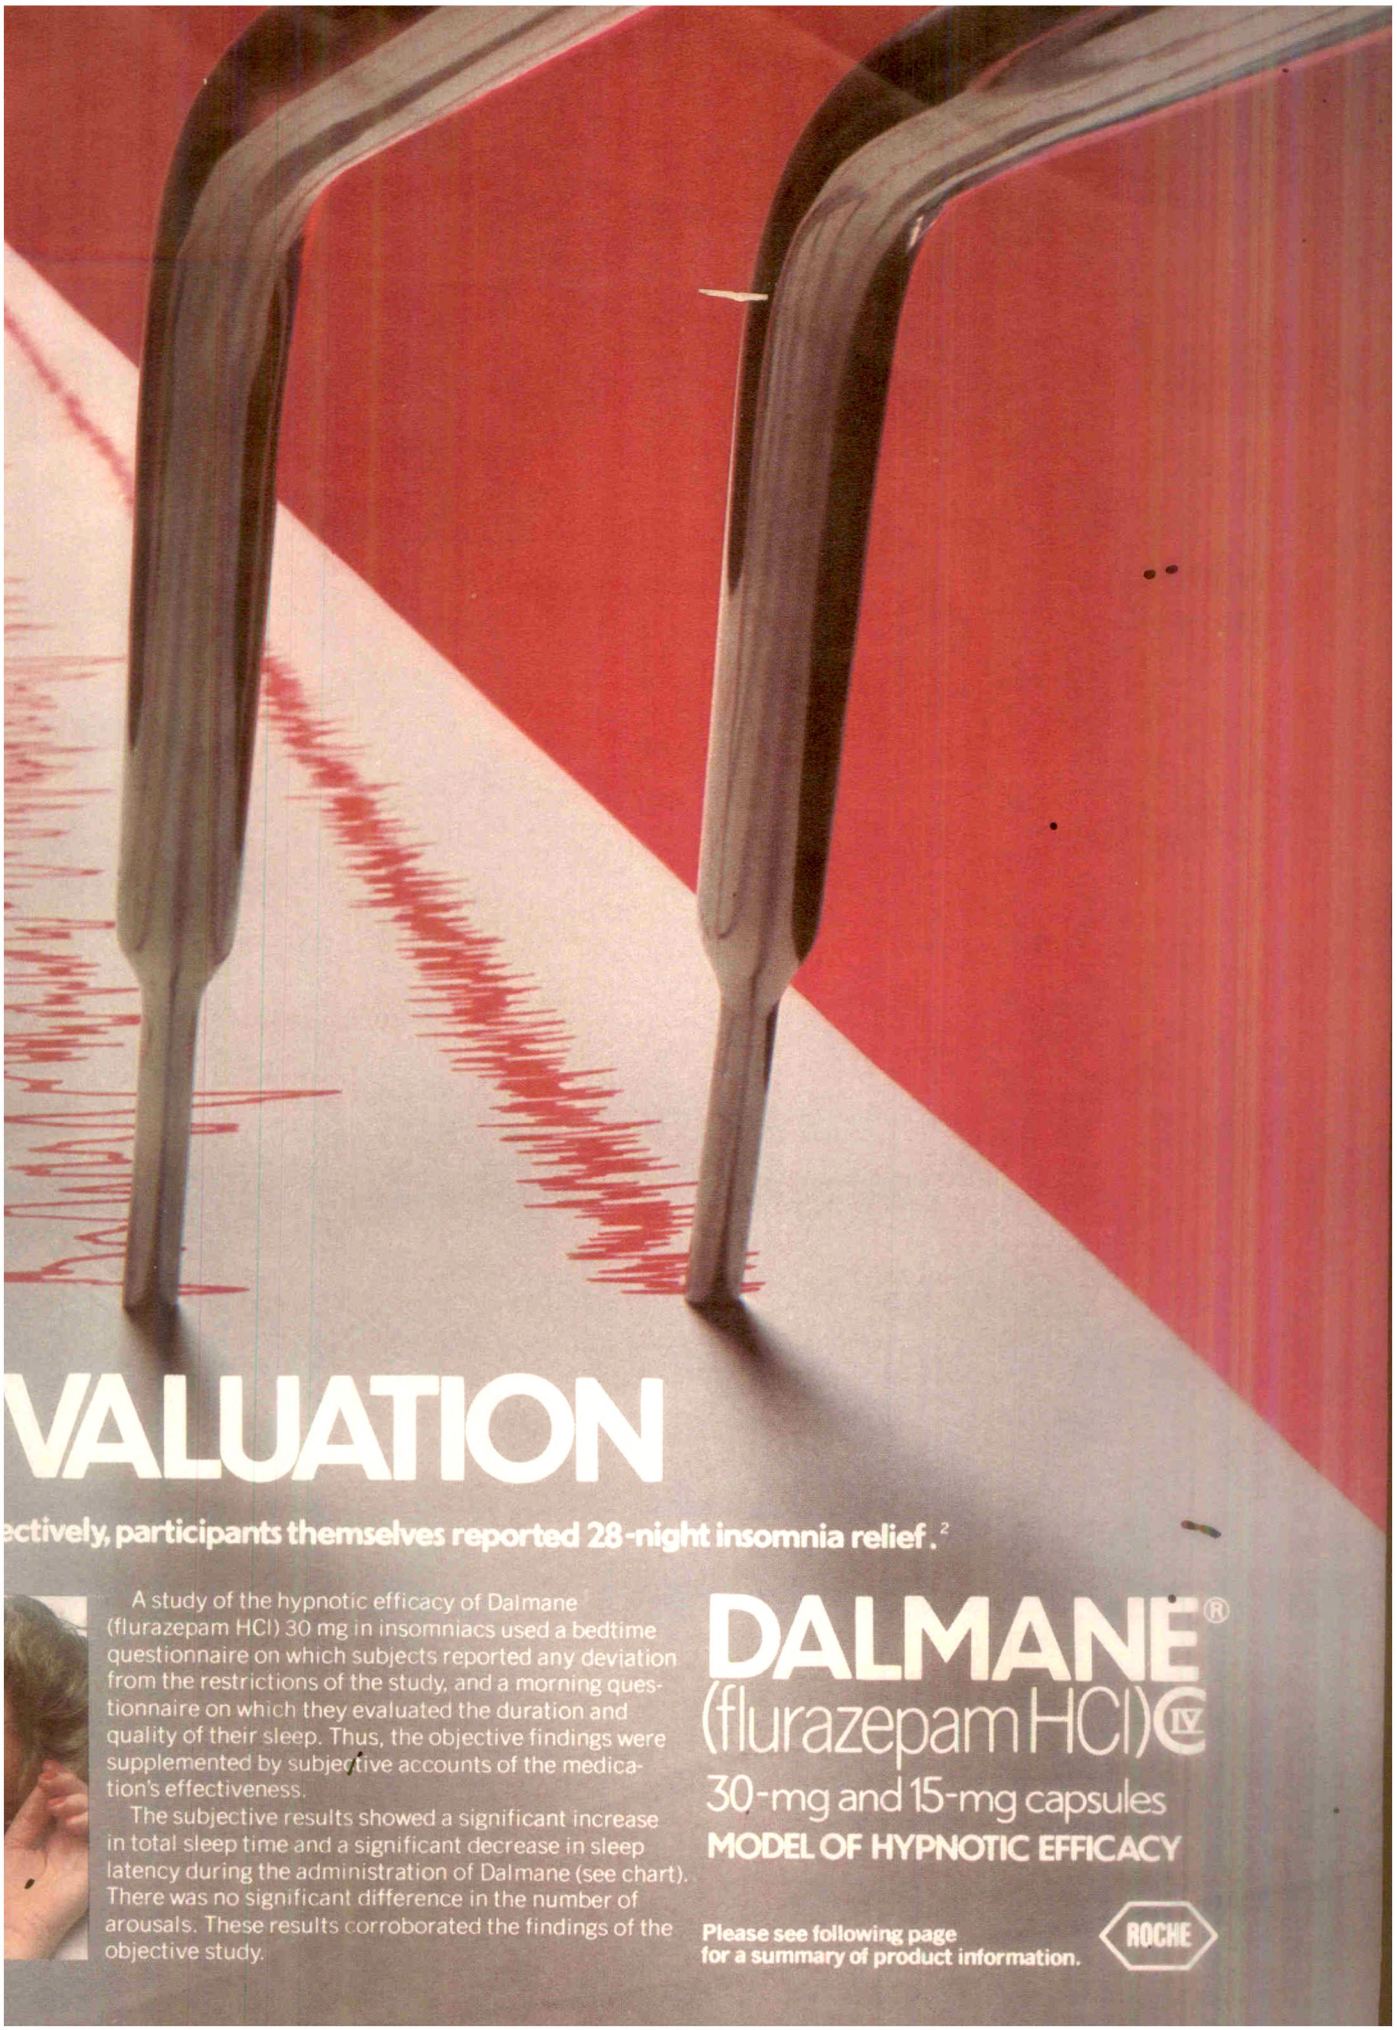
SLEEP

Objectively, the sleep laboratory proved relief of insomnia from the first through the 28th night.[1]

IMPROVEMENT IN SLEEP PARAMETERS OVER BASELINE DURING ADMINISTRATION OF DALMANE (flurazepam HCl)[2]
Mean Values of Averaged Nights 1-3, 12-14, 26-28



OBJECTIVE		SUBJECTIVE
62.5% less time	time required to fall asleep	45.6%† less time
23.3%† more time	total sleep time	18%† more time

Reductions in minutes required to fall asleep and increases in total sleep time were averaged and expressed as percentages.

A composite of six separate sleep laboratory studies of Dalmane®(flurazepam HCl) provides a comprehensive profile of hypnotic efficacy during short-, intermediate- and longer-term administration. Dalmane in 30 mg dosage was given to 23 insomnia patients for varying periods of time. Results showed that Dalmane was significantly effective in improving sleep induction and sleep maintenance. In addition, following discontinuation of Dalmane there was no sudden insomnia rebound.[1]

In another investigation of Dalmane 30 mg in five chronic insomniacs, the electro-physiologic evidence

eep time
me

VALUATION

ectively, participants themselves reported 28-night insomnia relief.[2]

A study of the hypnotic efficacy of Dalmane (flurazepam HCl) 30 mg in insomniacs used a bedtime questionnaire on which subjects reported any deviation from the restrictions of the study, and a morning questionnaire on which they evaluated the duration and quality of their sleep. Thus, the objective findings were supplemented by subjective accounts of the medication's effectiveness.

The subjective results showed a significant increase in total sleep time and a significant decrease in sleep latency during the administration of Dalmane (see chart). There was no significant difference in the number of arousals. These results corroborated the findings of the objective study.

DALMANE®
(flurazepam HCl) C IV
30-mg and 15-mg capsules
MODEL OF HYPNOTIC EFFICACY

Please see following page for a summary of product information.

ROCHE

28-NIGHT INSOMNIA RELIEF...
PROVED BY THE POLYGRAPH, CORROBORATED BY THE PATIENTS[2]

DALMANE®
(flurazepam HCl)

One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—recommended dosage for elderly or debilitated patients.

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Objective sleep laboratory data have shown effectiveness for at least 28 consecutive nights of administration. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).

Usage in Pregnancy: **Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane, a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated, limit dosage to 15 mg to reduce risk of oversedation, dizziness, confusion and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies, or with impaired renal or hepatic function. Periodic blood counts and liver and kidney function tests are advised during repeated therapy.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect.
Adults: 30 mg usual dosage; 15 mg may suffice in some patients.
Elderly or debilitated patients: 15 mg initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

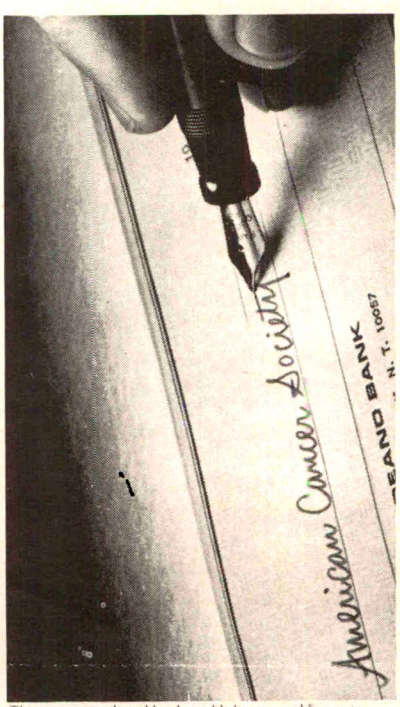
Help cure cancer write now.

Thanks to your help, the tide is beginning to turn. The past few years have brought new discoveries in chemotherapy.

And new diagnostic techniques that combine the "eyes" of X-ray machines with the "brains" of computers. And successful new programs of combination therapies.



And there are promising reports coming in from research laboratories all over the world.

We now have everything we need to save about half the people who get cancer.

Please don't quit on us now.

We're halfway there.

American Cancer Society
We want to cure cancer in your lifetime.

This space contributed by the publisher as a public service.

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

100-mg, 75-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE, 10 mg/ml, in 120-ml (4-oz) bottles

*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.

† The 150-mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions

ANTIDEPRESSANT EFFECTIVENESS

SINEQUAN®
(DOXEPIN HCl)

150-mg CAPSULE*

*The 150-mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have been reported occasionally. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN (doxepin HCl) in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy. Prescriptions should be written for the smallest feasible amount.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting daily dose of 75 mg is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg/day to 150 mg/day.

In more severely ill patients higher doses may be required with subsequent gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg/day.

The total daily dosage of SINEQUAN (doxepin HCl) may be given on a divided or once-a-day dosage schedule. If the once-a-day schedule is employed the maximum recommended dose is 150 mg/day. This dose may be given at bedtime. **The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.**

Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias and tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus), hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.

B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressive supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions to prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbed. The use of activated charcoal has been recommended, as has been continuous gastric lavage with saline for 24 hours or more. An adequate airway should be established in comatose patients and assisted ventilation used if necessary. EKG monitoring may be required for several days, since relapse after apparent recovery has been reported. Arrhythmias should be treated with the appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CNS symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intravenous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine is rapidly metabolized, the dosage should be repeated as required. Convulsions may respond to standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depression. Dialysis and forced diuresis generally are not of value in the management of overdosage due to high tissue and protein binding of SINEQUAN.

Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to: 10 mg, 75 mg, and 100 mg doxepin: bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). 25 mg and 50 mg doxepin: bottles of 100, 1000, 5000, and unit-dose packages of 100 (10 x 10's). 150 mg doxepin: bottles of 50, 500, and unit-dose packages of 100 (10 x 10's). SINEQUAN Oral Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 mg doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted with approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number of carbonated beverages. For those patients requiring antidepressant therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water; but not with grape juice. Preparation and storage of bulk dilutions is not recommended.

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

Awake on the job...

yet anxiety controlled

Troublesome drowsiness uncommon

Tranxene lets you manage anxiety in most patients without problem sedation. Any initial drowsiness is usually transient.

Calming without impairment

Patients not oversedated can function better on the job* or at home. By avoiding excessive sedation, Tranxene helps you calm patients without compromising their capacities.

ABBOTT

Tranxene®

(CLORAZEPATE DIPOTASSIUM)

IV 4306CB

Capsules: 3.75, 7.5, 15 mg; Tablets: 11.25, 22.5 mg

*Of course patients should be cautioned against hazardous tasks requiring mental alertness. See overleaf for prescribing information.

8083272R

Tranxene® CIV

(CLORAZEPATE DIPOTASSIUM) 4306CB

CAPSULES,
SINGLE DOSE TABLETS

Brief Summary

ACTIONS — Pharmacologically, clorazepate dipotassium has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine. (See CLINICAL PHARMACOLOGY section.)

INDICATIONS — TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS — TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS — TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS — In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS — The side effect most frequently reported was drowsiness. Less commonly reported (in descending order of occurrence) were: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects included insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION

For the symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For the symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg. TRANXENE initially, followed by 30 to 60 mg. in divided doses; 2nd 24 hours, 45 to 90 mg. in divided doses; 3rd 24 hours, 22.5 to 45 mg. in divided doses; 4th day, 15 to 30 mg. in divided doses. Thereafter gradually reduce to 7.5 to 15 mg. daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS — If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE — Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE (clorazepate dipotassium) as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY — Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

Absorption — Excretion:

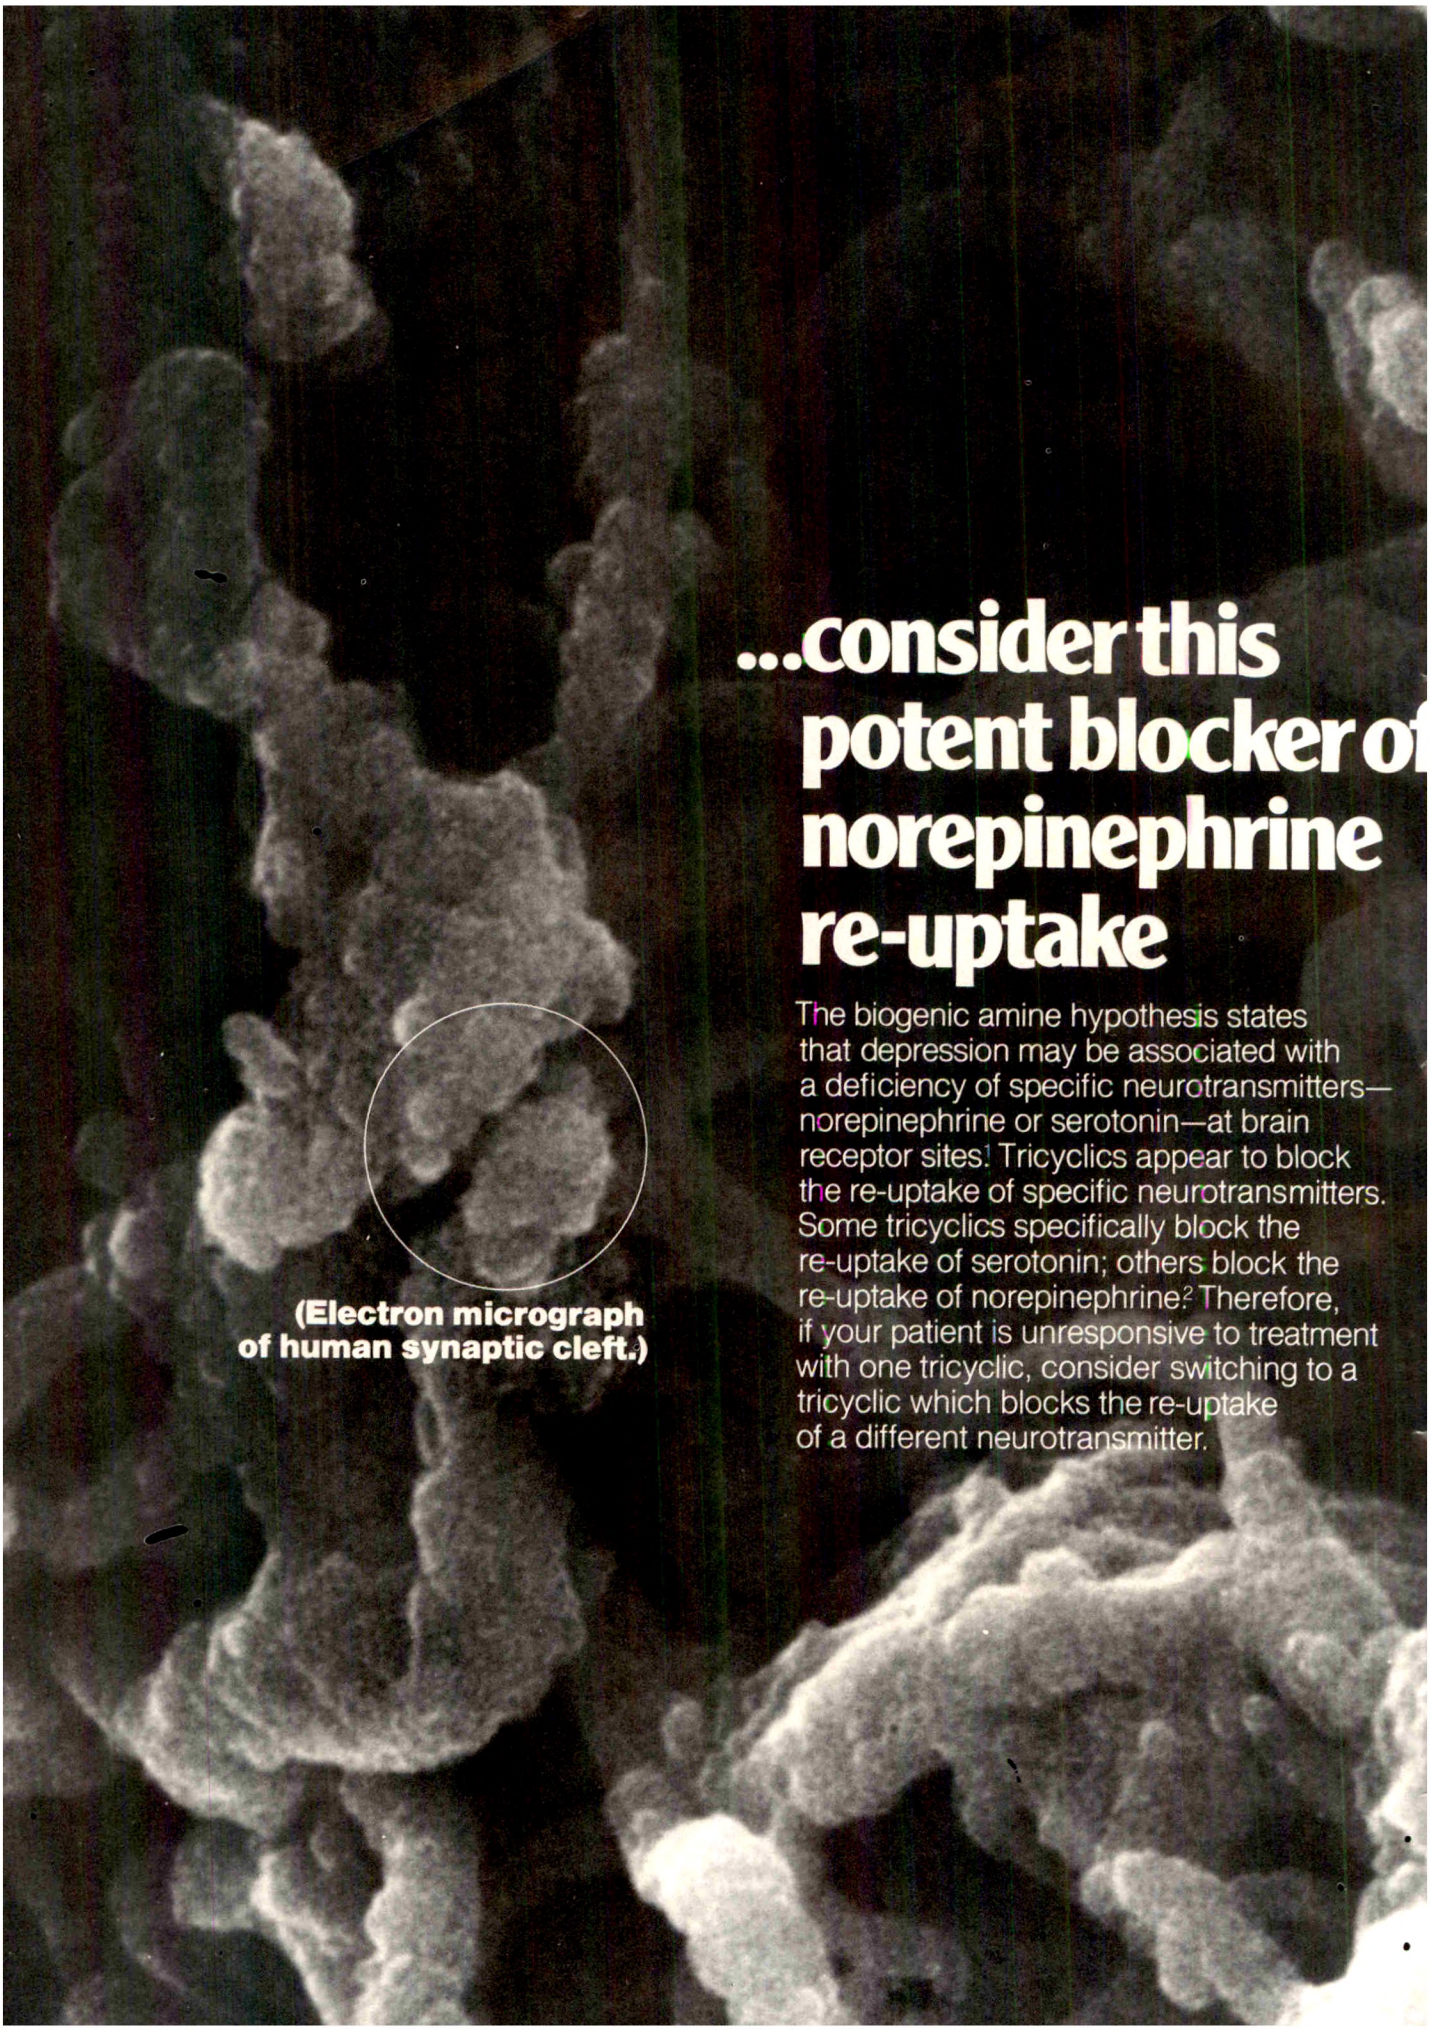
After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

HOW SUPPLIED — TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 30 (NDC 0074-3418-30), 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3418-11).

15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3419-11).



TRANXENE-SD single dose tablets are supplied in two dosage strengths:

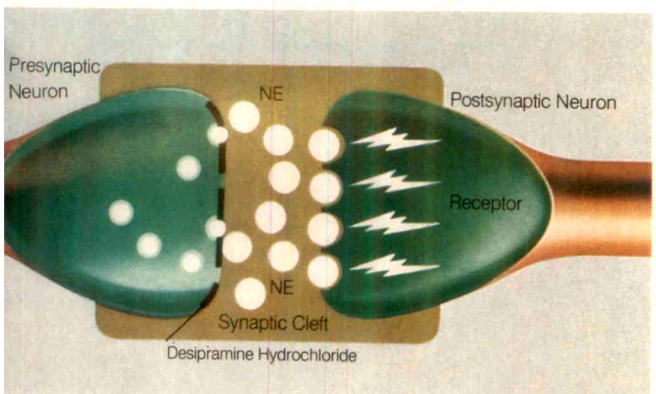
TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 30 (NDC 0074-2699-30) and 100 (NDC 0074-2699-13).

8083272

When your patient is clinically depressed...
"...everything I saw was negative."

...consider this potent blocker of norepinephrine re-uptake



The biogenic amine hypothesis states that depression may be associated with a deficiency of specific neurotransmitters—norepinephrine or serotonin—at brain receptor sites.[1] Tricyclics appear to block the re-uptake of specific neurotransmitters. Some tricyclics specifically block the re-uptake of serotonin; others block the re-uptake of norepinephrine.[2] Therefore, if your patient is unresponsive to treatment with one tricyclic, consider switching to a tricyclic which blocks the re-uptake of a different neurotransmitter.

(Electron micrograph of human synaptic cleft.)

Norpramin®
(desipramine hydrochloride tablets NF)
25, 50, 75, 100, 150 mg.

Potent blocker of norepinephrine re-uptake

According to current theory[1,3] some tricyclic antidepressants may fail in certain types of depression because they are not sufficiently potent blockers of norepinephrine re-uptake. Laboratory studies have shown that desipramine is the most potent inhibitor of norepinephrine re-uptake.[4] Norpramin may work in some patients when other tricyclic antidepressants do not.

Consider it now, consider it next.

Less anticholinergic activity

(See Warnings section.)

Studies in animals[5] and in normal human subjects[6,7] have shown that desipramine has significantly less anticholinergic activity than amitriptyline or doxepin. The single bond side chain is associated with lower anticholinergic activity than these other leading antidepressants. This may mean:

- less dry mouth
- less blurred vision
- less urinary retention

Helps patients remain calm but active

Norpramin does not usually inhibit normal activity although patients should be cautioned as to driving or operating machinery if drowsiness occurs.

In addition...

Begins to improve sleep patterns within one week in some patients[8]

- Norpramin helps relieve the sleep disturbances that often accompany depression.
- As the depression is relieved, the difficulty in falling asleep, restlessness, and early morning awakening diminish.

Merrell

Norpramin®
(desipramine hydrochloride tablets NF)

AVAILABLE ONLY ON PRESCRIPTION

Brief Summary

MECHANISM OF ACTION: Available evidence suggests that many depressions have a biochemical basis in the form of a relative deficiency of neurotransmitters such as norepinephrine and serotonin. Norepinephrine deficiency may be associated with relatively low urinary 3-methoxy-4-hydroxyphenyl glycol (MHPG) levels, while serotonin deficiencies may be associated with low spinal fluid levels of 5-hydroxyindolacetic acid.

While the precise mechanism of action of the tricyclic antidepressants is unknown, a leading theory suggests that they restore normal levels of neurotransmitters by blocking the re-uptake of these substances from the synapse in the central nervous system.

Evidence indicates that the secondary amine tricyclic antidepressants, including Norpramin, may have greater activity in blocking the re-uptake of norepinephrine. Tertiary amine tricyclic antidepressants, such as amitriptyline, may have greater effect on serotonin re-uptake.

Norpramin (desipramine hydrochloride) is not a monoamine oxidase (MAO) inhibitor and does not act primarily as a central nervous system stimulant. It has been found in some studies to have a more rapid onset of action than imipramine. Earliest therapeutic effects may occasionally be seen in 2 to 5 days, but full treatment benefit usually requires 2 to 3 weeks to obtain.

INDICATIONS: Norpramin (desipramine hydrochloride) is indicated for relief of symptoms in various depressive syndromes, especially endogenous depression.

CONTRAINDICATIONS: Desipramine hydrochloride should not be given in conjunction with, or within 2 weeks of, treatment with an MAO inhibitor drug; hyperpyretic crises, severe convulsions, and death have occurred in patients taking MAO inhibitors and tricyclic antidepressants. When Norpramin (desipramine hydrochloride) is substituted for an MAO inhibitor, at least 2 weeks should elapse between treatments. Norpramin should then be started cautiously and should be increased gradually.

The drug is contraindicated in the acute recovery period following myocardial infarction. It should not be used in those who have shown prior hypersensitivity to the drug. Cross sensitivity between this and other dibenzazepines is a possibility.

WARNINGS: **1.** Extreme caution should be used when this drug is given in the following situations: a. In patients with cardiovascular disease, because of the possibility of conduction defects, arrhythmias, tachycardias, strokes, and acute myocardial infarction. b. In patients with a history of urinary retention or glaucoma, because of the anticholinergic properties of the drug. c. In patients with thyroid disease or those taking thyroid medication, because of the possibility of cardiovascular toxicity, including arrhythmias. d. In patients with a history of seizure disorder, because this drug has been shown to lower the seizure threshold. **2.** This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. **3.** USE IN PREGNANCY: Safe use of desipramine hydrochloride during pregnancy and lactation has not been established; therefore, if it is to be given to pregnant patients, nursing mothers, or women of childbearing potential, the possible benefits must be weighed against the possible hazards to mother and child. Animal reproductive studies have been inconclusive. **4.** USE IN CHILDREN: Norpramin (desipramine hydrochloride) is not recommended for use in children since safety and effectiveness in the pediatric age group have not been established. **5.** The patient should be cautioned that this drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. **6.** In patients who may use alcohol excessively, it should be borne in mind that the potentiation may increase the danger inherent in any suicide attempt or overdosage.

PRECAUTIONS: **1.** It is important that this drug be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with this class of drug. Ordinary prudence requires that children not have access to this drug or to potent drugs of any kind; if possible this drug should be dispensed in containers with child-resistant safety closures. Storage of this drug in the home must be supervised responsibly. **2.** If serious adverse effects occur, dosage should be reduced or treatment should be altered. **3.** Norpramin (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates. **4.** The drug may cause exacerbation of psychosis in schizophrenic patients. **5.** Close supervision and careful adjustment of dosage are required when this drug is given concomitantly with anticholinergic or sympathomimetic drugs. **6.** Patients should be warned that while taking this drug their response to alcoholic beverages may be exaggerated. **7.** Clinical experience in the concurrent administration of ECT and antidepressant drugs is limited. Thus, if such treatment is essential, the possibility of increased risk relative to benefits should be considered. **8.** The sedative effects of Norpramin and benzodiazepines (*e.g.*, chlordiazepoxide or diazepam) are additive. Both the sedative and anticholinergic effects of the major tranquilizers are additive to those of Norpramin. **9.** This drug should be discontinued as soon as possible prior to elective surgery because of the possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients taking desipramine hydrochloride. **10.** Both elevation and lowering of blood sugar levels have been reported. **11.** Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

ADVERSE REACTIONS: Note: Included in the following listing are a few adverse reactions that have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when Norpramin (desipramine hydrochloride) is given.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic: numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus.

Anticholinergic: dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis, increased intraocular pressure; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs.

Hematologic: bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue.

Endocrine: gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

DOSAGE AND ADMINISTRATION: Not recommended for use in children. Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients compared to hospitalized patients, who are closely supervised. Dosage should be initiated at a low level and increased according to clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a period of time and should be at the lowest dose that will maintain remission.

Usual Adult Dose: The usual adult dose is 100 to 200 mg. per day. In more severely ill patients, dosage may be further increased gradually to 300 mg./day if necessary. Dosages above 300 mg./day are not recommended.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response.

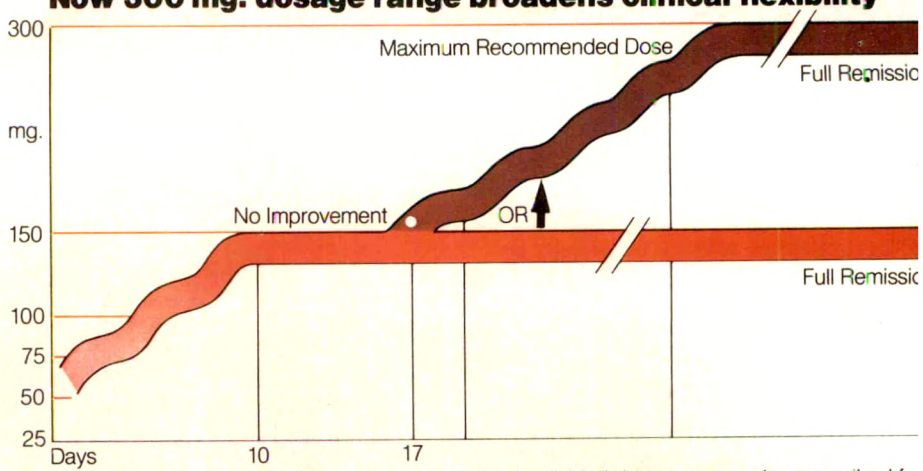
Treatment of patients requiring as much as 300 mg. should generally be initiated in hospitals, where regular visits by the physician, skilled nursing care, and frequent electrocardiograms (ECG's) are available.

The best available evidence of impending toxicity from very high doses of Norpramin is prolongation of the QRS or QT intervals on the ECG. Prolongation of the PR interval is also significant, but less closely correlated with plasma levels. Clinical symptoms of intolerance, especially drowsiness, dizziness, and postural hypotension, should also alert the physician to the need for reduction in dosage. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

Adolescent and Geriatric Dose: The usual adolescent and geriatric dose is 25 to 100 mg. daily.



Dosage should be initiated at a lower level and increased according to tolerance and clinical response to a usual maximum of 100 mg. daily. In more severely ill patients, dosage may be further increased to 150 mg./day. Doses above 150 mg./day are not recommended in these age groups.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

OVERDOSAGE: See prescribing information for a discussion of symptoms and treatment of overdose.

Product Information as of April, 1978

A maximum dosage of 300 mg. a day, as a single or divided dose, may now be prescribed for Norpramin. Since inadequate dosage is thought to be one of the major causes of treatment failure, the new therapeutic range should prove clinically helpful. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

They thought Ed Sloan was just tired...

maybe he had narcolepsy

A narcoleptic can fall asleep almost anywhere, anytime. The results can be at least embarrassing... at most devastating.

Narcolepsy is often unrecognized

As a primary sleep abnormality narcolepsy is characterized by inappropriate sleepiness, inappropriate sleep episodes, and cataplexy (episodes of muscular weakness precipitated by strong emotion). These are often accompanied by hypnagogic hallucinations, automatic behavior and/or disturbed nocturnal sleep. Sleep apnea may be a severe life-threatening complication of narcolepsy.

It is important to recognize that electroencephalographic studies provide a means of distinguishing narcolepsy from normal sleep.

Besides its medical implications, narcolepsy may have drastic social consequences. "All too often, the patient with disabling hypersomnolence is ignored by physicians for years and even decades, with the consequent tragic toll on his ability to learn and to work."[1]

Ritalin can help in narcolepsy

For narcoleptic sleepiness and sleep episodes, the cited authorities[1,2] most frequently use Ritalin (methylphenidate).

CIBA

Ritalin® C II
(methylphenidate)

For the narcoleptics who can't stay awake

Ritalin® hydrochloride C II
(methylphenidate hydrochloride USP)
TABLETS

INDICATION
Narcolepsy.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.

Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-Pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.

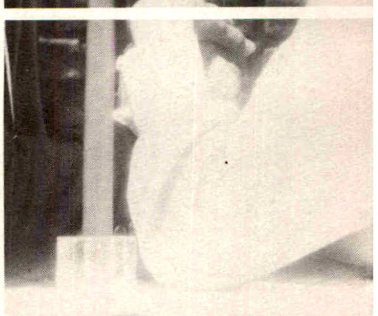
Merck Sharp & Dohme announces a new dosage strength

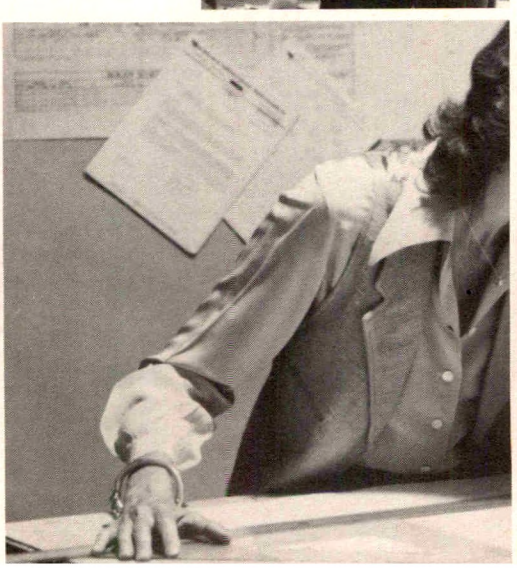
now dual-action Triavil® 4-50

containing 4 mg perphenazine and 50 mg amitriptyline HCl

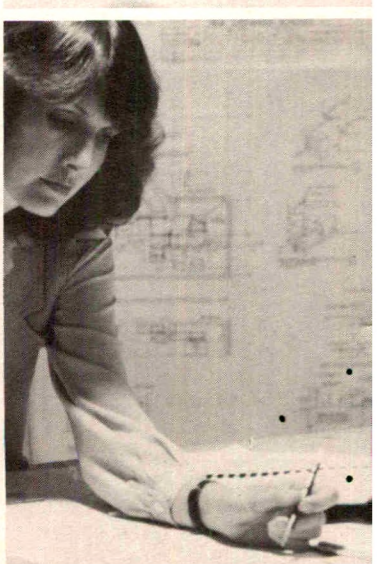
For even more dosage versatility in the treatment of marked agitation with depression



NEW dosage strength—to simplify therapy
five dosage strengths now available



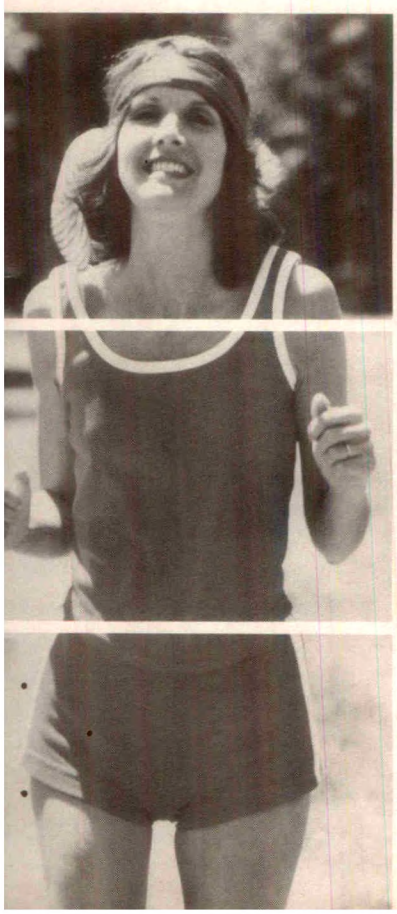
NEW option: b.i.d. regimen—to improve compliance
for initiating therapy
Rx TRIAVIL 4-50 b.i.d.



NEW unit-of-use package
bottles of 60 for 30 days of therapy, where appropriate

When TRIAVIL is part of the program, you may anticipate these therapeutic benefits for many patients:

Rapid antianxiety effect
The tranquilizer component can alleviate symptoms of anxiety and agitation within a few days. Hypnotic effects from the tranquilizer component appear to be minimal, particularly in patients permitted to remain active.



Highly effective antidepressant action
The antidepressant component can help relieve symptoms of depression such as poor concentration and feelings of hopelessness as well as early morning awakening; adequate relief of symptoms may take a few weeks or even longer.

...to aid the psychotherapeutic process
Patients often become more accessible and cooperative; symptomatic relief may enable the patient to function more effectively in his daily activities.

Treatment with TRIAVIL—a balanced view:
TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks such as operating machinery or driving. The drug may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD
MERCK SHARP & DOHME

Please see following page for a brief summary of prescribing information.

For a wide range of patients with marked agitation and depression

dual-action Triavil®
containing perphenazine and amitriptyline HCl

now offers more dosage strengths than any other formulation containing a tranquilizer and an antidepressant

dual-action Triavil®

containing perphenazine and amitriptyline HCl

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-50: Each tablet contains
4 mg perphenazine and 50 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides. There is sufficient experimental evidence to conclude that chronic administration of antipsychotic drugs which increase prolactin secretion has the potential to induce mammary neoplasms in rodents under the appropriate conditions. There are recognized differences in the physiological role of prolactin between rodents and humans. Since there are, at present, no adequate epidemiological studies, the relevance to human mammary cancer risk from prolonged exposure to perphenazine and other antipsychotic drugs is not known.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

FLEXIBLE DOSAGE TO MEET THE INTENSITY OF ANXIETY

□ for clinically manifest neurotic or psychoneurotic anxiety, and anxiety associated with somatic disease†

Approximate Milligram Equivalency*

AZENE™ Clorazepate monopotassium	Diazepam	Chlordi-azepoxide	Oxazepam
3.25 mg	2 mg	5 mg	10 mg
6.5 mg	5 mg	10 mg	15 mg
13.0 mg	10 mg	25 mg	30 mg

*Based upon available information from manufacturers' package inserts.

□ an acceptable sedative profile

Drowsiness may occur at initiation of treatment, and with dosage increments.

Brief Summary of Prescribing Information

CONTRAINDICATIONS AZENE™ (clorazepate monopotassium) is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS AZENE™ is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on AZENE™ should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since AZENE™ (clorazepate monopotassium) has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, AZENE™ is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence: Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepates. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Tolerance developed within 3 to 9 days in dogs. Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during the first trimester of pregnancy has been suggested in several studies. AZENE™ (clorazepate monopotassium) a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to

†The effectiveness of AZENE™ in long-term use, that is, more than four months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

AZENE™ (clorazepate monopotassium) should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Periodic blood counts and liver function tests are advisable for patients on AZENE™ for prolonged periods. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS The side effect most frequently reported with the use of benzodiazepines is drowsiness. Less commonly reported side effects are: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects include insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit. Decrease in systolic blood pressure has been observed with clorazepates.

DRUG INTERACTIONS If AZENE™ (clorazepate monopotassium) is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that clorazepates prolong the sleeping time after hexobarbital or after ethyl alcohol, increase the inhibitory effects of chlorpromazine, but do not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If AZENE™ is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

HOW SUPPLIED AZENE™ (clorazepate monopotassium) is supplied as 3.25 mg and 6.5 mg capsules in bottles of 100 and 500, and as 13 mg capsules in bottles of 100.

ASSISTANT SUPERINTENDENT FOR PROFESSIONAL SERVICES

New Hampshire Hospital, Concord, N.H., an 800 bed JCAH-Accredited psychiatric hospital, is seeking an Assistant Superintendent for Professional Services to be responsible for the direction and coordination of clinical programs for the treatment, care and management of mentally ill patients. New Hampshire Hospital, the only public psychiatric hospital in N.H., is located in Concord, a city of approximately 30,000 people, 75 minutes north of Boston, MA. Salary to $41,690. Possibility of facutly appointment to major university. Housing and other fringe benefits are available. Candidate must be a physician-psychiatrist licensed or eligible for licensure as an M.D. in New Hampshire and certified or eligible for certification by the American Board of Neurology and Psychiatry.

Interested applicants should contact C. Clifton DuBois, Ph.D., Superintendent at New Hampshire Hospital, 105 Pleasant Street, Concord, New Hampshire 03301. Telephone (603) 271-2205.

LIAISON and INPATIENT PSYCHIATRISTS WANTED

Bd. cert. or elig. required. Chillicothe VA Hospital is a 1000-bed hosp. with large aftercare program. JCAH approved. OSMA approved cont. med. ed. prog. for AMA Phy. Recognition Award. Hosp. located in southern Ohio natural recreation and scenic area, 45-min. from Columbus. Financial assistance in moving. Equal Employment Opportunity Employer. Write Chief of Staff, VA Hospital, Chillicothe, OH 45601 or call 614-773-1141, ext. 202.

ASSISTANT DIRECTOR FOR PSYCHIATRY

Immediate opening for Assistant Director in Department of Psychiatry in 375 bed general teaching hospital in Fort Worth, Texas. Teaching and patient care programs are being developed through affiliation with Department of Psychiatry of Southwestern Medical School at Dallas.

Psychiatrist will assist Director to provide direct patient care, teaching rotating residents, and clinically supervise acute and intermediate treatment programs in two units totaling 58 beds. Therapeutic milieu is eclectic with emphasis on interpersonal, humanistic and psychodynamic approaches. Multidisciplinary professional staff includes four masters level therapists. Many services locally available for patient referrals including outpatient clinic, partial hospitalization, alcohol treatment, vocational development centers, and others.

Fort Worth, Texas is a major and growing metropolitan area of 400,000 people and well known for its low cost of living. Many recreational facilities for water activities, hunting, golf, amateur and professional sports and more. Cultural, educational, and entertainment opportunities are excellent.

Faculty appointment and remuneration will be based on clinical and academic experience.

Please forward curriculum vitae with your initial response to:

Director, Department of Psychiatry
Tarrant County Hospital District
1500 South Main Street
Fort Worth, Texas 76104

MEDICAL AND PSYCHIATRIC DIRECTOR THE BROWN SCHOOLS

We are looking for a board certified child psychiatrist to provide leadership for the medical and clinical staffs of our three JCAH accredited psychiatric facilities, our halfway houses, and our two group homes. Our present program has a capacity of over 525 residents, and expansion is planned into other states in the near future.

Applicants for this position should be experienced in the field of residential treatment and be capable in the areas of administrative duties and responsibilities. Salary is open based on qualifications and excellent fringe benefits are provided. Qualified applicants should send a curriculum vita to:

William Porcher, M.D.
Chairman — Search Committee
P.O. Box 4008
Austin, Texas 78765

In depression...

3 of 10 patients will fail to respond to initial therapy.

make

PERTOFRANE® (desipramine HCl NF)

your first choice for the 3 of 10 patients who don't respond.

because of:

- **CLINICAL EFFECTIVENESS** even when "most patients had a history of several depressive episodes, hospitalizations, ECT or poor response to numerous other drugs."[1]

- **LOW SIDE EFFECTS PROFILE** with less sedating properties than amitriptyline or doxepin[2] and less anticholinergic activity.[3]

- **ENHANCED PATIENT ACCEPTANCE** through a flexible dosage schedule plus rapid onset of action.

PERTOFRANE® when they don't respond.
(desipramine HCl NF)

USV LABORATORIES
USV Laboratories Inc.
Manati, P.R. 00701

Please see next page for brief summary of prescribing information and references.

PERTOFRANE®
(desipramine HCl NF)

Indication: For relief of mental depression. **Contraindications:** Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane (desipramine HCl) in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. The potentiation resulting from excessive use of alcohol may increase the danger inherent in a suicide attempt or overdosage. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine. **Dosage:** All patients except geriatric and adolescent: 75 to 150 mg./day in divided doses or as single daily dose. Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Therapy may be given in divided doses or as a single daily dose. **How Supplied:** 25 mg. capsules (pink), bottles of 100 and 1000. Also, 50 mg. capsules (maroon and pink), bottles of 100 and 1000.

Prescribing Information for

Lidone™ (molindone hydrochloride)

DESCRIPTION — LIDONE (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

LIDONE is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4(5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

ACTIONS — LIDONE (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, LIDONE antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, LIDONE exerts its effect on the ascending reticular activating system.

Human metabolic studies show LIDONE (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24 to 36 hours. There are 36 recognized metabolites with less than 2 to 3% unmetabolized LIDONE being excreted in urine and feces.

INDICATIONS — LIDONE (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS — LIDONE (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats Oral Dose —
20 mg/kg/day — 10 days, no adverse effect
40 mg/kg/day — 10 days, no adverse effect

Pregnant Mice Oral Dose —
20 mg/kg/day — 10 days, slight increase resorptions
40 mg/kg/day — 10 days, slight increase resorptions

Pregnant Rabbits Oral Dose —
5 mg/kg/day — 12 days, no adverse effect
10 mg/kg/day — 12 days, no adverse effect
20 mg/kg/day — 12 days, no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of LIDONE (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of LIDONE (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS — Some patients receiving LIDONE (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving LIDONE. Caution should be exercised where increased activity may be harmful.

LIDONE does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

LIDONE has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS

CNS Effects — The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological Extrapyramidal Reactions — Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia — Motor restlessness may occur early.

Parkinson Syndrome — Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome — Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System — Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological — There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with LIDONE may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects — Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with LIDONE therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with LIDONE.

Cardiovascular — Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological — Lens opacities and pigmentary retinopathy have not been reported where patients have received LIDONE (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with LIDONE.

Skin — Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with LIDONE usage alone.

LIDONE (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when LIDONE is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia — Although rarely reported with LIDONE (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION — Initial and maintenance doses of LIDONE (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50 to 75 mg/day.
- Increase to 100 mg/day in three or four days.
- Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- An increase to 225 mg/day may be required in patients with severe symptomatology.
- Some chronic, treatment-resistant patients may require up to 400 mg/day; (however, the long-term safety of 400 mg/day has not been established).

Elderly or debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild — 5 mg to 15 mg three or four times a day.
2. Moderate — 10 mg to 25 mg three or four times a day.
3. Severe — 225 mg/day may be required.

Dosage may be administered once a day.

DRUG INTERACTIONS — Potentiation of drugs administered concurrently with LIDONE (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when LIDONE is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE — Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of LIDONE (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of LIDONE (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by LIDONE in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized LIDONE from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of LIDONE is excreted unmetabolized in the urine.) However, poor response of the patient may justify use of these procedures.

While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized LIDONE in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED — LIDONE (molindone hydrochloride) capsules are supplied in bottles of 100 in the following dosage strengths and colors:

5 mg (**NDC** 0074-5542-13) blue and cream
10 mg (**NDC** 0074-5543-13) red and cream
25 mg (**NDC** 0074-5544-13) brown and cream

Genetic Counseling for Psychiatric Patients and Their Families

By Ming T. Tsuang

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

BACK HOME

THORAZINE®

brand of

CHLORPROMAZINE

Tablets:
50 and 100 mg.
of the HCl

Home from the hospital. He went in with a psychiatric emergency but left more like himself—delusions, hallucinations, and other psychotic target symptoms under control with 'Thorazine'. And 'Thorazine' maintenance can help keep him out of the hospital in the future.

From initial psychiatric emergency through maintenance therapy, 'Thorazine' offers effective antipsychotic therapy with 18 convenient dosage forms and strengths. This means you can precisely tailor dosage to the individual patient's needs throughout the entire course of therapy.

'Thorazine'. The most widely tested and highly flexible antipsychotic available today.

Helps return psychotic patients to reality

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: The possibility of extrapyramidal reactions from 'Thorazine' may confuse the diagnosis of Reye's syndrome or other encephalopathy. Therefore, avoid use in children or adolescents with suspected Reye's syndrome.

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or obscure diagnosis of conditions such as intestinal obstruction, brain tumor, and Reye's syndrome (see Warnings). Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only).
Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.
Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

UNDERSTANDING THE RAPE VICTIM

A Synthesis of Research Findings

Sedelle Katz & Mary Ann Mazur

Is the rape victim responsible for her predicament? What happens to the victim who reports the crime? What about those that don't? Are there any long-term psychological effects? These are just some of the many questions and issues this informative, authoritative reference confronts. Based on empirical data gathered from hundreds of publications, it provides an in-depth analysis of the rape victim as she appears before, during, and after the assault.

COUNSELING AND PSYCHOTHERAPY

A Behavioral Approach

E. Lakin Phillips

This book examines the adaptation and use of behavioral therapy techniques in outpatient counseling and psychotherapy. Phillips presents a balanced exposition of how to begin, conduct, conclude, and evaluate the treatment. Techniques are designed to help patients understand their problems as well as the factors that contributed to them. The author also discusses behavior, examines behavioral techniques, and discusses therapeutic supervision in a behavioral framework.

(1-01881-3) 1977 289 pp. $20.95

ALCOHOLISM AND TREATMENT

David J. Armor, J. Michael Polich, & Harriet B. Stambul

Here's the most extensive national assessment of alcoholism and its treatment ever conducted. Based on the widely discussed Rand Corporation study, this book reports on data collected from alcoholism treatment centers throughout the country. It suggests that, contrary to general opinion, alcoholism can be treated successfully in most cases and argues that success can take many forms, including both abstention and moderate drinking.

A Theory of Interdependence

Harold H. Kelley & John W. Thibaut

This important new theoretical framework for the study of social interaction is the most thorough analysis of interdependence available. It examines possible variations in the nature of interdependence and the causes and consequences of these variations, providing insight into the general nature and origin of social motivation and social norms.

(1-03473-8) 1978 341 pp. $18.95

THE RORSCHACH

A Comprehensive System, Vol. 2 Current Research and Advanced Interpretations

John E. Exner, Jr.

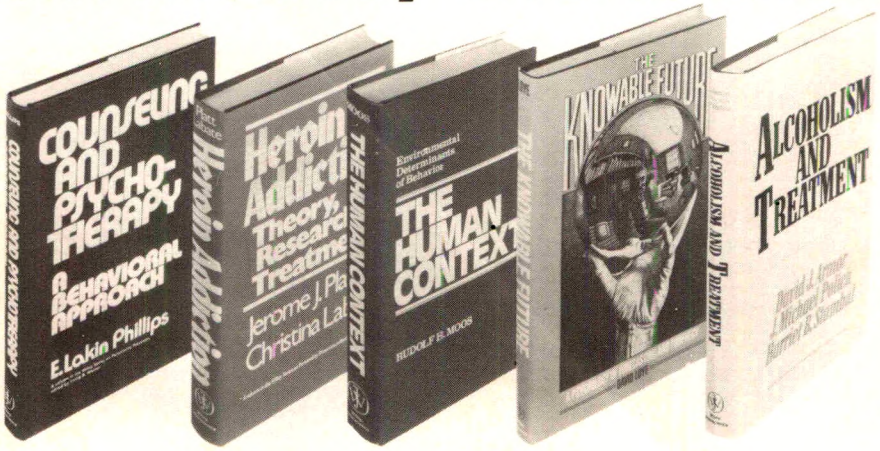
A continuation of the COMPREHENSIVE SYSTEM, this volume integrates the positive findings of all work to date into a system which is easily taught, manifests a high interclinician reliability, and stands well against the various tests of its validity. It presents a summary of research within the comprehensive system after 1973, combining these findings into the process of Rorschach interpretation.

(1-04166-1) 1978 448 pp. $32.95

THE KNOWABLE FUTURE

A Psychology of Forecasting and Prophecy

David Loye



Loye outlines a theoretically advanced, yet practical, down-to-earth psychology for futures forecasting. The author's new theory examines how the future is shaped and predicted according to the "matrix impact" of liberalism, conservatism, and five other major factors of ideology.

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, and are not being considered for publication elsewhere. Papers with multiple authors are reviewed with the assumption that all authors have approved them.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. All submissions must be accompanied by a cover letter *signed by all authors* and using the following wording:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. The cover letter in such cases should contain the following wording and should be signed by all authors:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 2–3 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by the appropriate cover letter, including the copyright transfer statement, will not be reviewed until such a statement is received.

Authors will be notified as soon as possible of the receipt of their paper; at this time, the paper will be assigned a number that must be included in all further correspondence. It is imperative that authors of papers under consideration notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in *final form*, i.e., are ready for review. Authors must *not* submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions, and not all papers can be published in the *Journal*. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; this number must appear in any further communications about the paper. The copyright transfer statement described above must accompany annual meeting papers submitted for review.

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent, including references, tables, and figures (about 15 manuscript pages). Brief Communications—2,500 words or equivalent (about 10 manuscript pages). Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures can be used in this section). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 25 double-spaced pages (about 7,500 words) and should have no more than 100 references. All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures or references, etc. Single case reports will not be accepted as regular articles or Brief Communications; these papers should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and *no figures*) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular or Brief Communication length (a "prompt publication policy" is automatically in effect for Clinical and Research Reports). These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality, and authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed *double-spaced* throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review or listing may be sent directly to the Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. Book reviews are usually solicited by the editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer. Reviews are usually less than 500 words long, seldom contain references, and will be edited.

TYPING AND ARRANGING THE PAPER

All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) *nonerasable* bond paper. All parts of the manuscript, including case reports, quotations, references, and tables, must be double-spaced throughout. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Please include degrees (other than honorary or undergraduate) after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. The authors' position titles and affiliations should be given in a paragraph using complete sentences. A full address is necessary only for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications (no précis is used in the Clinical and Research Reports section). The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material; a complete review of the literature is rarely desirable. *Accuracy of citation is the author's responsibility.* References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do *not* arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below and on the next page, double-spaced *throughout* (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26

2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information available in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

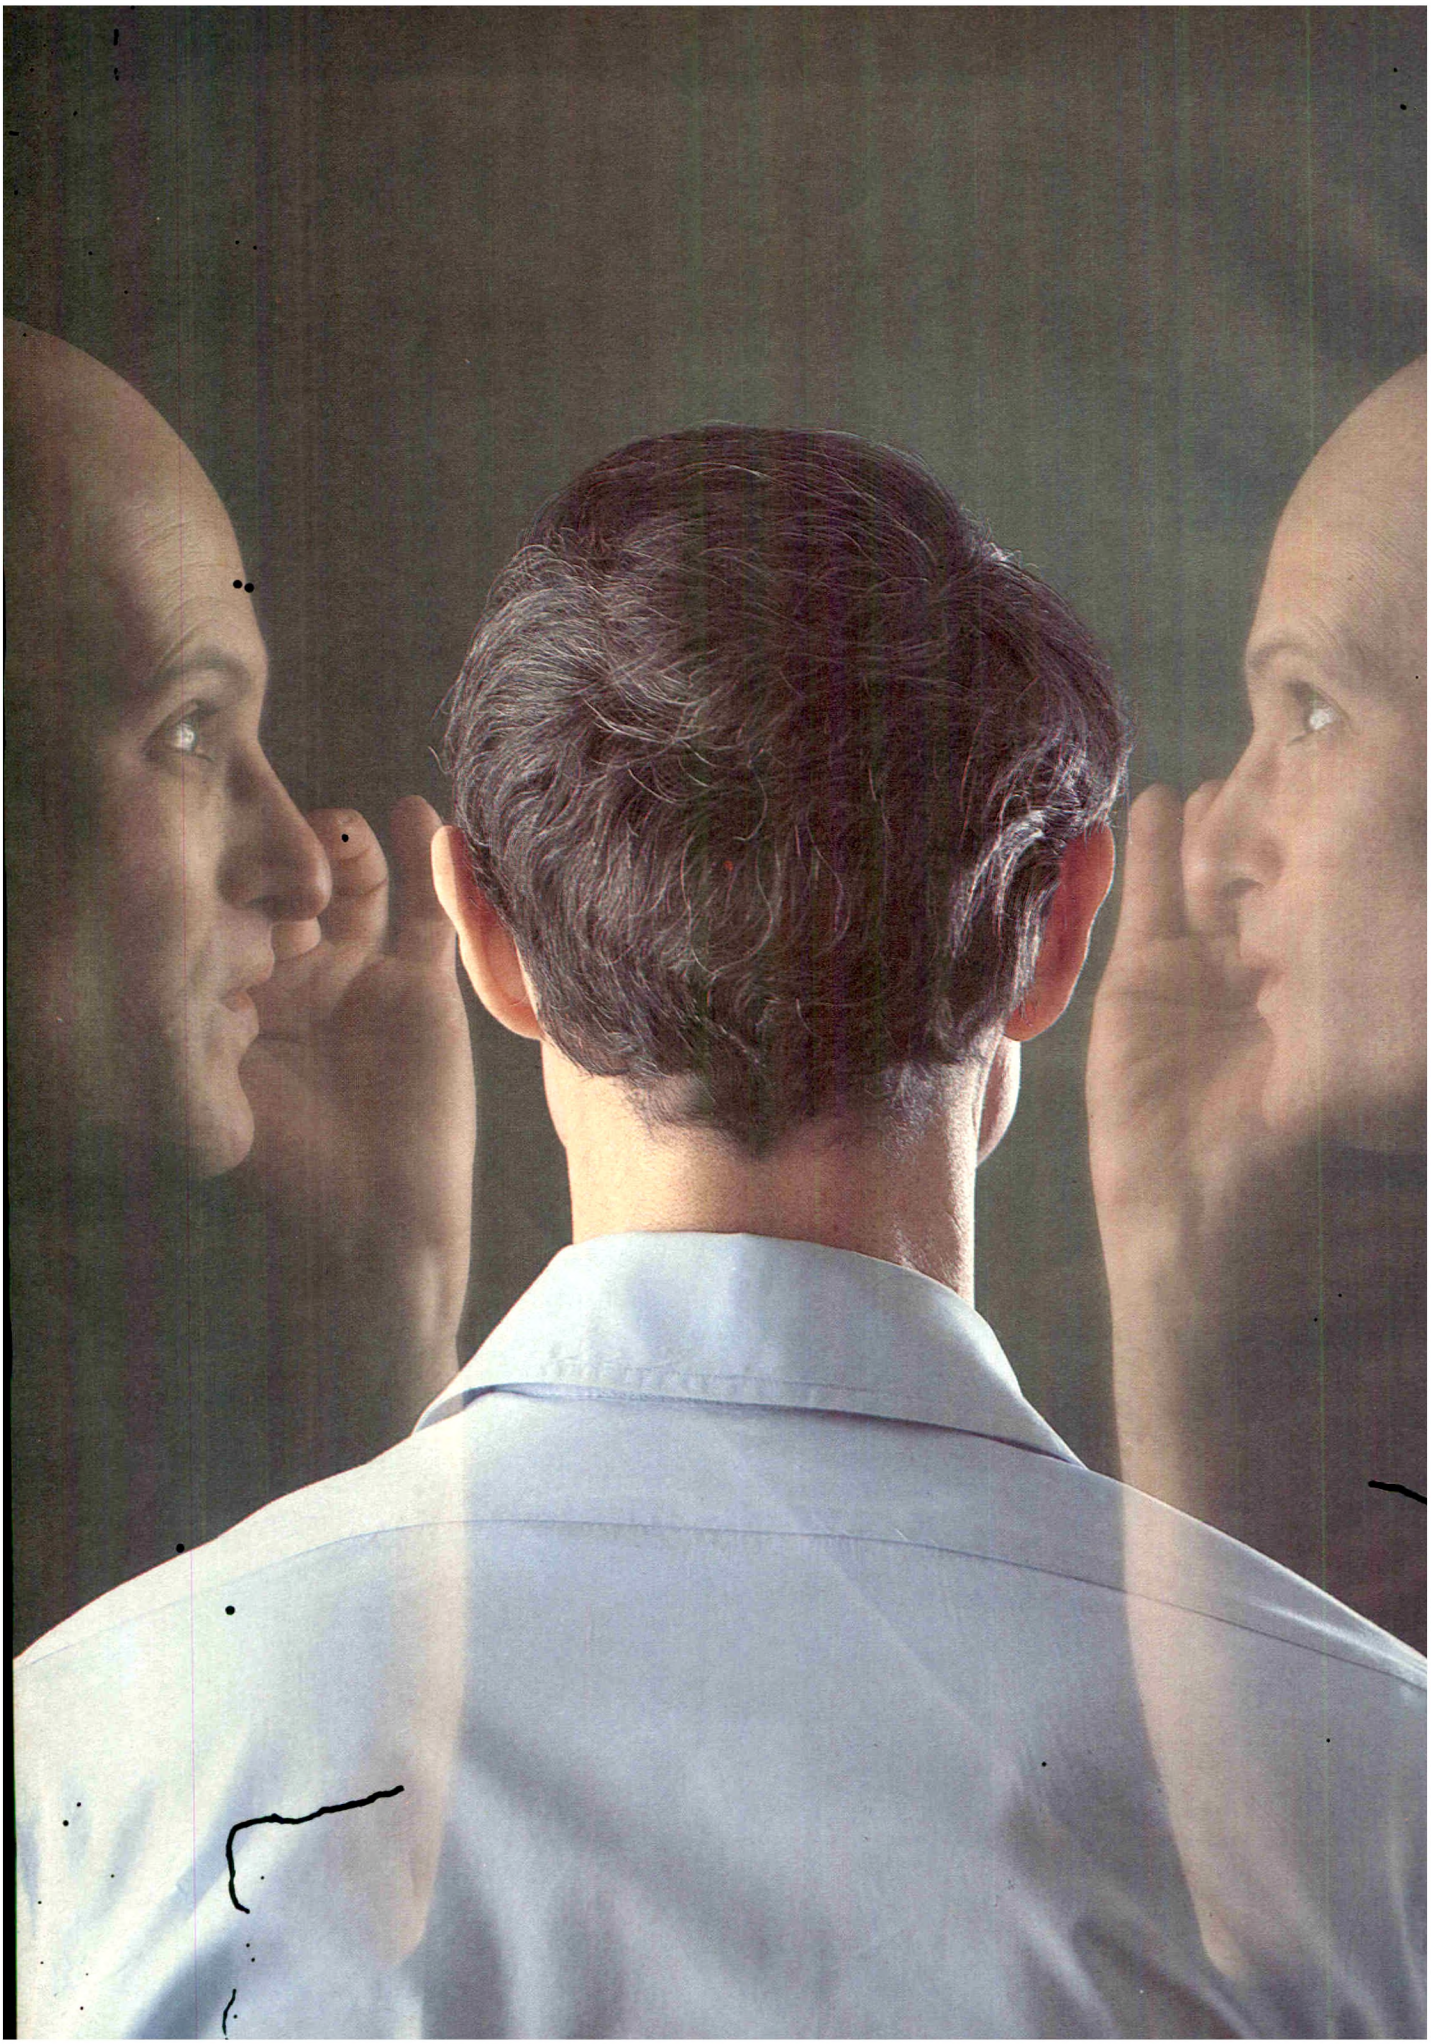
Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit use for educational purposes or of an author who wishes to reprint his/her own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS



No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article. Reprint orders from others should be directed to the APA Publications Services Division; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

  NIMH Collaborative Program

VOICES
...accusatory, derogatory, condemning, commanding.

Navane (thiothixene) rapidly controls auditory hallucinations as well as the agitation and hostility patterns they frequently generate.

Rapid control of psychotic symptoms on admission

Navane provides effective, rapid control of the major symptoms of psychosis including hallucinations, delusions, agitation, hostility, and thought disorders.[1-5] Navane promotes rapid progress, usually without the over-sedation or cardiovascular problems that can impede the therapeutic course.

Continued long-term improvement

Because Navane provides long-term outpatient control of psychotic symptoms, it can enable many patients to function effectively at home and on the job and to adjust rapidly to the community.[6]

Effectiveness rarely compromised by adverse reactions

Navane allows patients to remain alert and active, seldom causing over-sedation or drowsiness.[7] Hypotension and other cardiovascular reactions[5,6,8] are seldom reported and the occurrence of unpleasant anticholinergic side effects such as dry mouth or constipation is rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled through dosage adjustments or antiparkinson agents.

Rapid control
Long-term improvement

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane* (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*—Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

QUICK HELPFUL INFORMATION FOR PHYSICIANS

Reaching therapeutic dosages

Reduction of unwanted side effects

Maintaining good remissions

Increasing the % of patients who will respond to drug therapy

Drug compliance

FOR THE ABOVE ASSAYS, GAS CHROMATOGRAPHY WITH A NITROGEN DETECTOR IS USED. THIS METHODOLOGY GIVES VALUES CONSISTENT WITH THOSE REPORTED IN CLINICAL AND RESEARCH LITERATURE.

...with a low incidence of adverse side effects on

MOBAN®
molindone HCl

- an effective antipsychotic agent
- not a phenothiazine

FAVORABLE BENEFIT/RISK PROFILE, WHICH MAY ENHANCE COMPLIANCE*

NO incidence	Tolerance development Hepatotoxic changes Ophthalmological changes Excessive weight gain Impotence Decreased libido Skin pigmentation Thyroid function changes Persistent tardive dyskinesia
LOW incidence	Sedation Adverse drug interactions Hypotension Hematological changes Lactation Amenorrhea Autonomic changes Skin rash Nonpersistent symptoms of tardive dyskinesia
MODERATE incidence	Extrapyramidal reactions

*This table compiled from clinical and field reports, according to the best available information.

Further advantages with MOBAN®

The pharmacological effect from a single oral dose persists for 24-36 hours, permitting *h.s.* dosage, once the daily dosage level is established.

Several clinicians have reported that obese patients on MOBAN® frequently experienced a marked reduction in weight toward normal weight.

How to use MOBAN®

The usual starting dose is 50-75 mg/day. You can increase to 100 mg/day in 3-4 days. Titrate individually up or down depending on patient response. Some chronic, treatment-resistant patients may require an increase to 400 mg/day. (However, the long-term safety of 400 mg/day has not been established.) Please refer to complete prescribing information for further dosage instructions.

For complete prescribing information, please see next page.

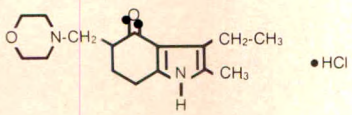
DUPONT

Patients become easier to manage on



MOBAN®

molindone HCl

5 mg	10 mg	25 mg
Endo	Endo	Endo

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN® Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although rarely reported with MOBAN® (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized.

Initial Dosage Schedule

The usual starting dosage is 50-75 mg/day.

—Increase to 100 mg/day in 3 or 4 days.

—Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.

—An increase to 225 mg/day may be required in patients with severe symptomatology.

—Some chronic, treatment resistant patients, may require up to 400 mg/day (however, the long term safety of 400 mg/day has not been established).

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule

1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

Dosages may be administered once a day.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN® in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencies and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

The easiest way multiply and divide

Adds better dosage control

(+) Long term treatment of depression with amitriptyline requires careful dosage titration to meet the individual needs of each patient. Because all six strengths of Endep (amitriptyline HCl) are scored, you can easily change the dose by half-tablet steps, without waiting for the patient to fill a new prescription.

to add, subtract, amitriptyline...

Subtracts some of the drawbacks of antidepressant therapy

(−) Scored Endep (amitriptyline HCl) tablets may eliminate the need for a new prescription each time the dosage needs to be changed, saving time for you and money for your patient. And, by keeping the patient on the same strength tablet, there's less chance he'll become confused, as he might if changed to another size or color of amitriptyline.

Multiplies therapeutic options

(×) The pharmacokinetic properties of Endep (amitriptyline HCl) are such that its clinical effect is the same whether prescribed *t.i.d.* or as a single daily dose. Thus, once you have established the proper dosage, you can prescribe the entire dose *h.s.*, minimizing anticholinergic and sedative side effects and helping to assure patient compliance with this simple regimen.

By prescribing the higher strength tablets *h.s.*—secure in the knowledge that the dosage can be adjusted in half-tablet steps without resorting to a new prescription—your patient will economize further on a per milligram basis.

Endep®
amitriptyline HCl/Roche

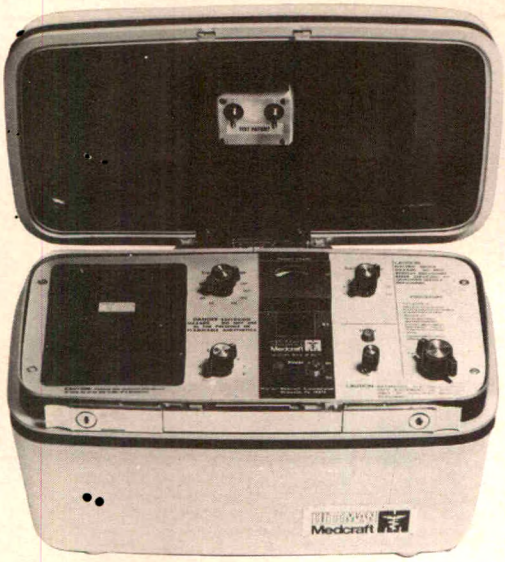
The only amitriptyline scored for easy division

Endep
amitriptyline HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle-closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.



Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Supplied: *Scored Tablets:* 10, 25, 50, 75, 100, 150 mg.

ROCHE

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Precise, easy-to-use

The B24 III SERIES Electroconvulsive THERAPY INSTRUMENTS

Designed to provide the physician with the ultimate in precision dosage, with consistency of output assured by the following:

- *Line Voltage Compensation*—Automatically adjusts variations in line voltage.
- *Pre-programmed Voltage Selection*—Offers a choice of 11 voltage levels, from 70 to 170 volts.
- *Automatic Treatment Timing*—Will adjust from 0.1 second to 1.0 second, with or without Glissando
- *Current Output Indicators*—During treatment current flow is clearly indicated.

Exclusive Patient Test Module allows a complete systems integrity check prior to treatment. 100% solid state circuitry assures clinical accuracy and dependability.

The B24 III series meets all requirements for Underwriters Laboratories—UL 544, Standards for Medical and Dental Equipment.

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION (Required by 39 U.S.C. 3685)

1. Date of filing: September 9, 1978.

2. Title of publication: THE AMERICAN JOURNAL OF PSYCHIATRY.

3. Frequency of issue: monthly. A. No. of issues published annually — 12. B. Annual subscription price — $18.00.

4. Location of known office of publication: 1700 18th St., N.W., Washington, D.C. 20009.

5. Location of the headquarters or general business offices of the publishers: 1700 Eighteenth St., N.W., Washington, D.C. 20009.

6. Names and addresses of publisher, editor, and managing editor: American Psychiatric Association, address 1700 18th St., N.W., Washington, D.C. 20009; Editor: John C. Nemiah, M.D., above address; Managing Editor: Evelyn S. Myers, above address.

7. Owner (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding 1 percent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a partnership or other unincorporated firm, its name and address, as well as that of each individual must be given): American Psychiatric Association, 1700 Eighteeenth St., N.W., Washington, D.C. 20009.

8. Known bondholders, mortgagees, and other security holders owning or holding 1 percent or more of total amount of bonds, mortgages or other securities (If there are none, so state): None.

9. For completion by nonprofit organizations authorized to mail at special rates (Section 132.122, PSM). The purpose, function, and nonprofit status of this organization and the exempt status for Federal income tax purposes have not changed during the preceding 12 months.

10. Extent and nature of circulation: Average no. copies each issue during preceding 12 months: A. Total no. copies printed (net press run): 33,471; B. Paid circulation: 1. Sales through dealers and carriers, street vendors and counter sales: None; 2. Mail subscriptions: 31,280; C. Total paid circulation (Sum of 10B1 and 10B2): 31,280; D. Free distribution by mail, carrier or other means — samples, complimentary, and other free copies: 524; E. Total distribution (Sum of C and D): 31,804; F. Copies not distributed — 1. Office use, left-over, unaccounted, spoiled after printing: 1,667; 2. Returns from News Agents: none; G. Total (Sum of E, F1 and F2 — should equal net press run shown in A): 33,471.

Actual number of copies of single issue published nearest to filing date: A. Total no. copies printed (net press run): 33,644; B. Paid circulation: 1. Sales through dealers and carriers, street vendors and counter sales: None; 2. Mail subscriptions: 31,956; C. Total paid circulation (Sum of 10B1 and 10B2): 31,956; D. Free distribution by mail, carrier or other means — samples, complimentary, and other free copies: 555; E. Total distribution (Sum of C and D): 32,511; F. Copies not distributed — 1. Office use, left-over, unaccounted, spoiled and after printing: 1,133; 2. Returns from News Agents: None; G. Total (Sum of E, F1 and F2 — should equal net press run shown in A): 33,644.

11. I certify that the statements made by me above are correct and complete.

NANCY FREY

12. For completion by publishers mailing at the regular rates *(Section 132.121, Postal Service Manual)*

39 U. S. C. 3626 provides in pertinent part: "No person who would have been entitled to mail matter under former section 4359 of this title shall mail such matter at the rates provided under this subsection unless he files annually with the Postal Service a written request for permission to mail matter at such rates."

In accordance with the provisions of this statute, I hereby request permission to mail the publication named in Item 1 at the phased postage rates presently authorized by 39 U. S. C. 3626.

One way to evaluate seizure etiology

Computerized transaxial tomography (CT scan) is an important new noninvasive techniqu
that can help in determining the etiology of epileptic seizures. Shown here is a single slice
from a color-enhanced CT scan of the brain of a patient with epilepsy. The absence of vas
abnormalities, tumor, or other lesions is compatible with a diagnosis of idiopathic epilepsy.

A proven way to start seizure control

MYSOLINE®
(primidone)

Tablets 50 mg, 250 mg
Suspension 250 mg/5 ml

A single entity with multiple anticonvulsant properties

Primidone itself has anticonvulsant activity. In addition, its major metabolite, phenylethylmalonamide (PEMA), exerts an anticonvulsant effect of its own and also enhances the anticonvulsant action of the second metabolite, phenobarbital. In patients refractory to phenytoin and phenobarbital, primidone may prove effective as the sole therapy.[1]

Multiple indications—grand mal, psychomotor, and focal epileptic seizures

In grand mal, MYSOLINE is comparable in efficacy to phenytoin and phenobarbital.[2,3] In psychomotor seizures, phenobarbital is rarely effective.[1] In focal seizures, phenytoin used alone is not indicated[4]—and, according to Forster,[3] MYSOLINE is markedly more effective than phenobarbital, which should dispel the misconception that MYSOLINE is "just a phenobarbital." (See chart below.)

Efficacy ratings* of anticonvulsants in epilepsy

Agent	Grand Mal	Psychomotor	Focal
Mysoline	++++	++++	++++
Hydantoinates (phenytoin)	++++	+++	+++
Barbiturates (phenobarbital)	++	++	++

* Relative effectiveness, ++++ being most effective.
Adapted from Forster, F. M.[3]

Consider it first for major motor epilepsies

MYSOLINE® (primidone) Ayerst®

See next page for Brief Summary and references.

Start seizure control with MYSOLINE® (primidone)

Initial dose in children over 8 years of age and adults: 250 mg daily at bedtime

BRIEF SUMMARY
(For full prescribing information, see package circular.)
MYSOLINE®
Brand of **PRIMIDONE** *Anticonvulsant*

ACTIONS: MYSOLINE raises electro- or chemoshock seizure thresholds or alters seizure patterns in experimental animals. The mechanism(s) of primidone's antiepileptic action is not known.

Primidone *per se* has anticonvulsant activity as do its two metabolites, phenobarbital and phenylethylmalonamide (PEMA). In addition to its anticonvulsant activity, PEMA potentiates that of phenobarbital in experimental animals.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several weeks before it can be assessed.

Usage in pregnancy: The effects of MYSOLINE in human pregnancy and nursing infants are unknown.

Recent reports suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Data are more extensive with respect to diphenylhydantoin and phenobarbital, but these are also the most commonly prescribed anticonvulsants; less systematic or anecdotal reports suggest a possible similar association with the use of all known anticonvulsant drugs.

The reports suggesting an elevated incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodologic problems in obtaining adequate data on drug teratogenicity in humans; the possibility also exists that other factors, *e.g.*, genetic factors or the epileptic condition itself, may be more important than drug therapy in leading to birth defects. The great majority of mothers on anticonvulsant medication deliver normal infants. It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

PRECAUTIONS: The total daily dosage should not exceed 2 g. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 g per day. The initial dose is 250 mg. Increments of 250 mg are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 g. A typical dosage schedule for the introduction of MYSOLINE is as follows:

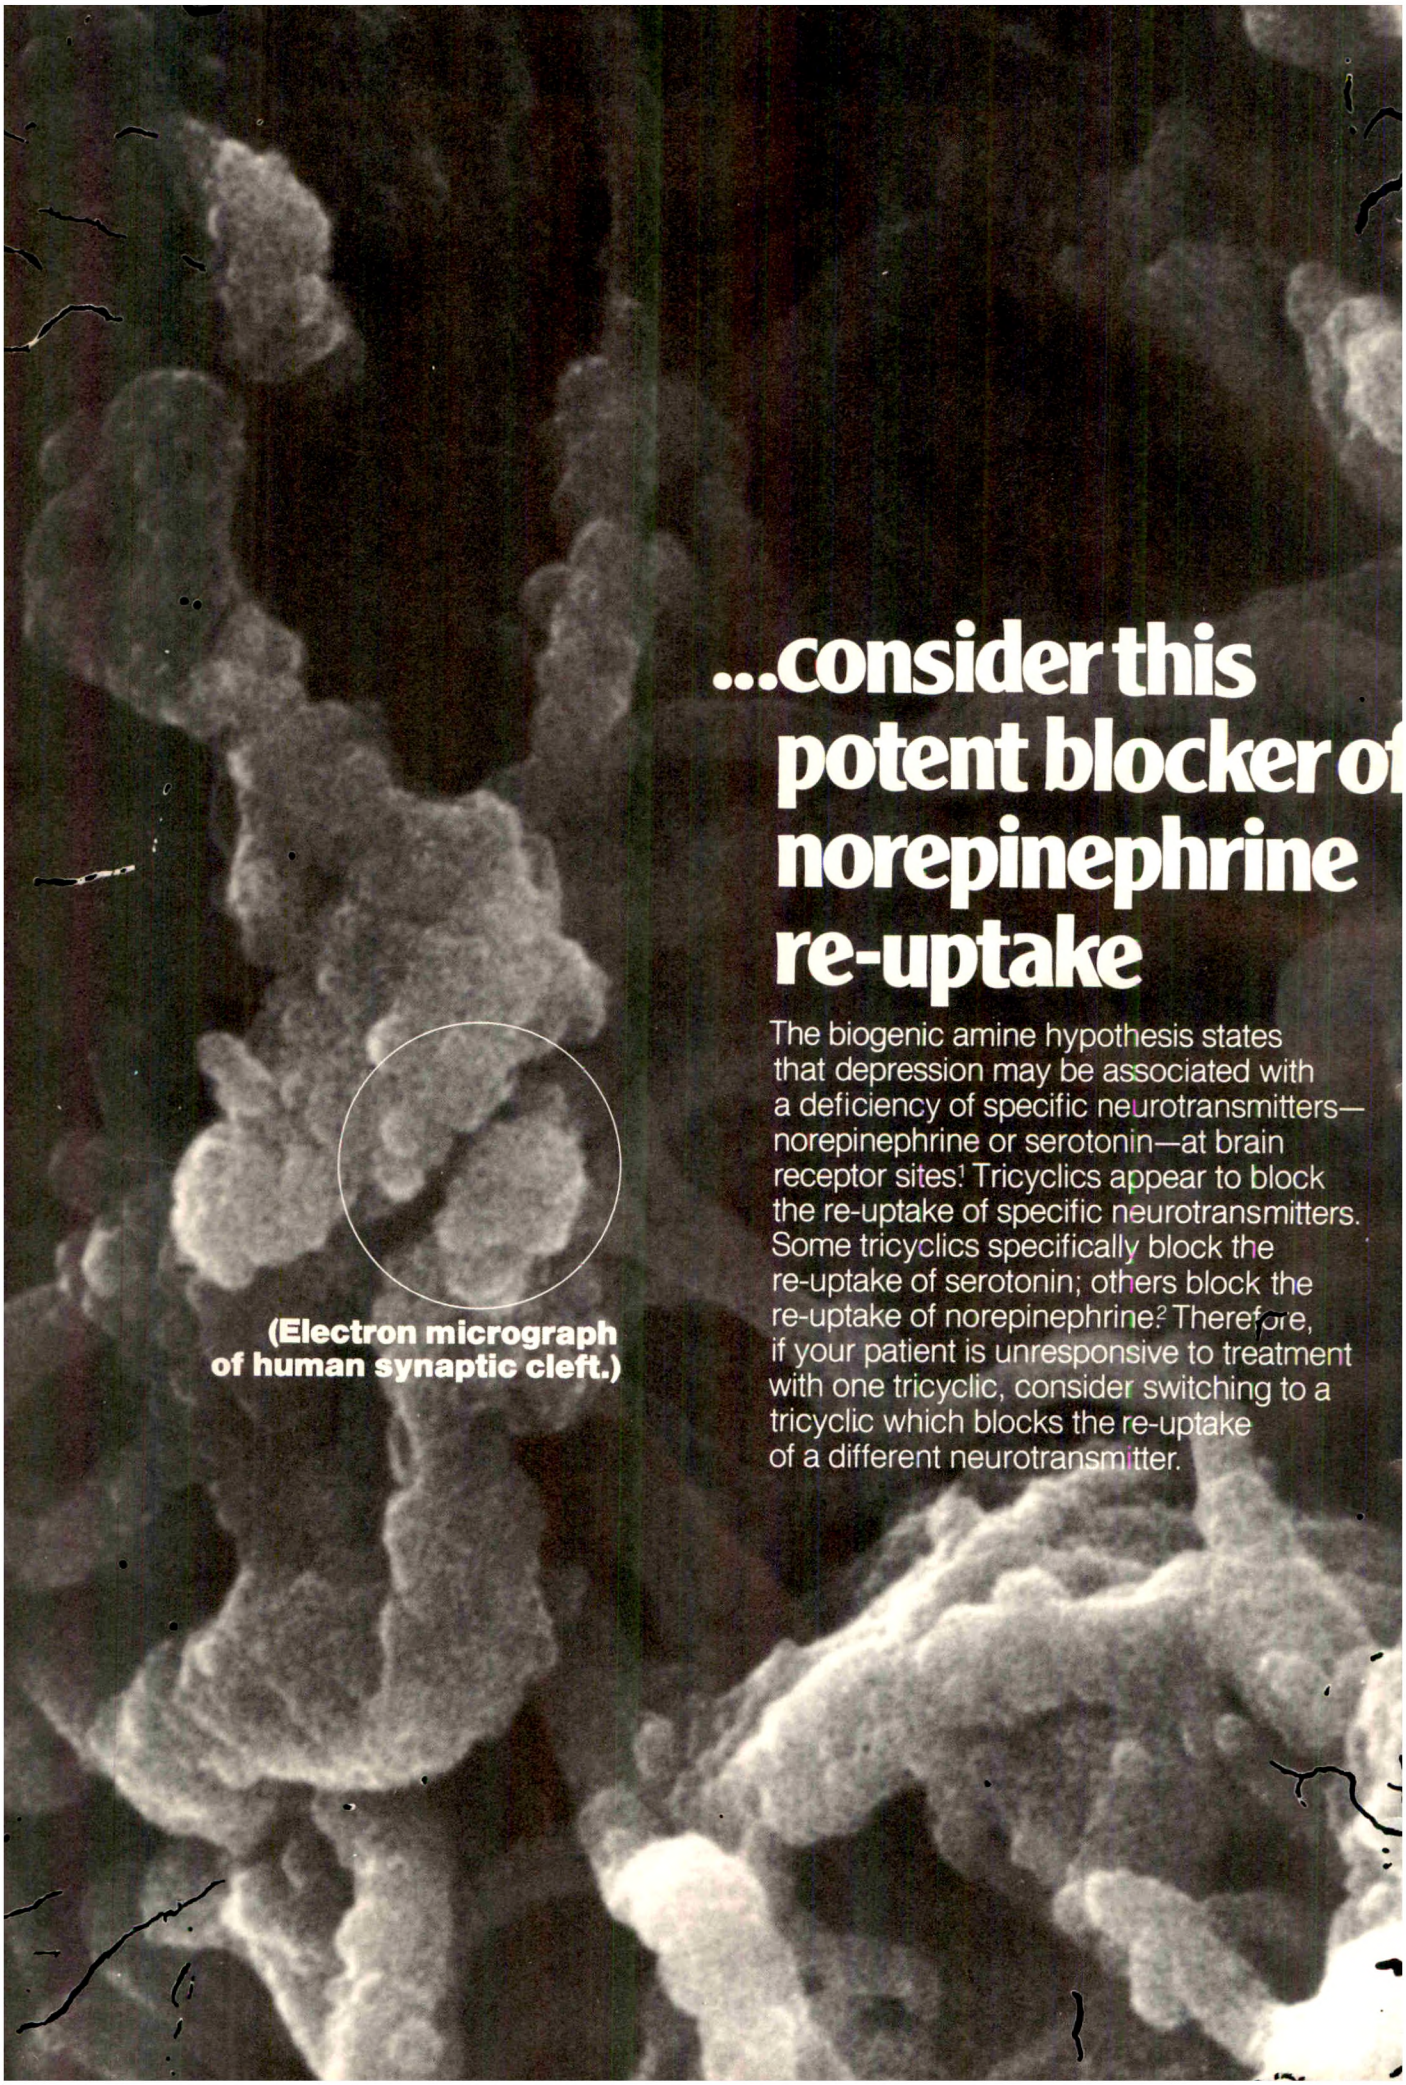
Adults and Children Over 8 Years of Age

1st Week 250 mg daily at bedtime	*2nd Week* 250 mg b.i.d.
3rd Week 250 mg t.i.d.	*4th Week* 250 mg q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg, with gradual weekly increases of 125 mg a day, to a daily total usually between 500 mg and 750 mg.

In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances: for initiation of combination therapy; during "transfer" therapy; for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.).



HOW SUPPLIED: MYSOLINE Tablets—No. 430—Each tablet contains 250 mg of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg of primidone (scored), in bottles of 100 and 500.
MYSOLINE Suspension—No. 3850—Each 5 ml (teaspoonful) contains 250 mg of primidone, in bottles of 8 fluidounces.

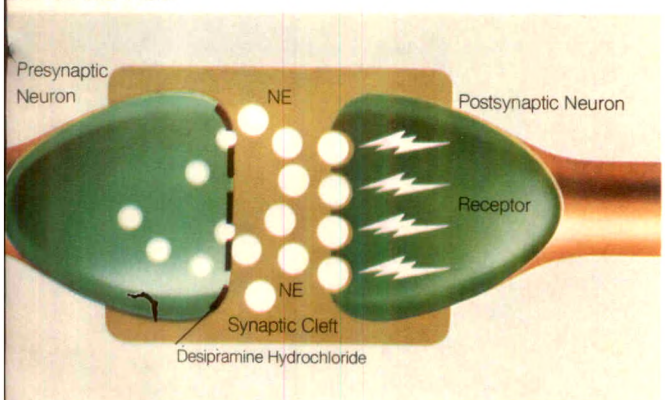
Ayerst® Ayerst Laboratories
New York, N.Y. 10017

7827

When your patient is clinically depressed...
"...everything I saw was negative."

...consider this potent blocker of norepinephrine re-uptake

The biogenic amine hypothesis states that depression may be associated with a deficiency of specific neurotransmitters—norepinephrine or serotonin—at brain receptor sites.[1] Tricyclics appear to block the re-uptake of specific neurotransmitters. Some tricyclics specifically block the re-uptake of serotonin; others block the re-uptake of norepinephrine.[2] Therefore, if your patient is unresponsive to treatment with one tricyclic, consider switching to a tricyclic which blocks the re-uptake of a different neurotransmitter.



(Electron micrograph of human synaptic cleft.)

Norpramin®
(desipramine hydrochloride tablets NF)

25, 50, 75, 100, 150 mg.

Potent blocker of norepinephrine re-uptake

According to current theory[1,3] some tricyclic antidepressants may fail in certain types of depression because they are not sufficiently potent blockers of norepinephrine re-uptake. Laboratory studies have shown that desipramine is the most potent inhibitor of norepinephrine re-uptake.[4] Norpramin may work in some patients when other tricyclic antidepressants do not.

Consider it now, consider it next.

Less anticholinergic activity

(See Warnings section.)

Studies in animals[5] and in normal human subjects[6,7] have shown that desipramine has significantly less anticholinergic activity than amitriptyline or doxepin. The single bond side chain is associated with lower anticholinergic activity than these other leading antidepressants. This may mean:

- less dry mouth
- less blurred vision
- less urinary retention

Helps patients remain calm but active

Norpramin does not usually inhibit normal activity although patients should be cautioned as to driving or operating machinery if drowsiness occurs.

In addition...

Begins to improve sleep patterns within one week in some patients[8]

- Norpramin helps relieve the sleep disturbances that often accompany depression.
- As the depression is relieved, the difficulty in falling asleep, restlessness, and early morning awakening diminish.

Merrell

Norpramin®
(desipramine hydrochloride tablets NF)

AVAILABLE ONLY ON PRESCRIPTION

Brief Summary

MECHANISM OF ACTION: Available evidence suggests that many depressions have a biochemical basis in the form of a relative deficiency of neurotransmitters such as norepinephrine and serotonin. Norepinephrine deficiency may be associated with relatively low urinary 3-methoxy-4-hydroxyphenyl glycol (MHPG) levels, while serotonin deficiencies may be associated with low spinal fluid levels of 5-hydroxyindolacetic acid.

While the precise mechanism of action of the tricyclic antidepressants is unknown, a leading theory suggests that they restore normal levels of neurotransmitters by blocking the re-uptake of these substances from the synapse in the central nervous system.

Evidence indicates that the secondary amine tricyclic antidepressants, including Norpramin, may have greater activity in blocking the re-uptake of norepinephrine. Tertiary amine tricyclic antidepressants, such as amitriptyline, may have greater effect on serotonin re-uptake.

Norpramin (desipramine hydrochloride) is not a monoamine oxidase (MAO) inhibitor and does not act primarily as a central nervous system stimulant. It has been found in some studies to have a more rapid onset of action than imipramine. Earliest therapeutic effects may occasionally be seen in 2 to 5 days, but full treatment benefit usually requires 2 to 3 weeks to obtain.

INDICATIONS: Norpramin (desipramine hydrochloride) is indicated for relief of symptoms in various depressive syndromes, especially endogenous depression.

CONTRAINDICATIONS: Desipramine hydrochloride should not be given in conjunction with, or within 2 weeks of, treatment with an MAO inhibitor drug; hyperpyretic crises, severe convulsions, and death have occurred in patients taking MAO inhibitors and tricyclic antidepressants. When Norpramin (desipramine hydrochloride) is substituted for an MAO inhibitor, at least 2 weeks should elapse between treatments. Norpramin should then be started cautiously and should be increased gradually.

The drug is contraindicated in the acute recovery period following myocardial infarction. It should not be used in those who have shown prior hypersensitivity to the drug. Cross sensitivity between this and other dibenzazepines is a possibility.

WARNINGS: 1. Extreme caution should be used when this drug is given in the following situations: a. In patients with cardiovascular disease, because of the possibility of conduction defects, arrhythmias, tachycardias, strokes, and acute myocardial infarction. b. In patients with a history of urinary retention or glaucoma, because of the anticholinergic properties of the drug. c. In patients with thyroid disease or those taking thyroid medication, because of the possibility of cardiovascular toxicity, including arrhythmias. d. In patients with a history of seizure disorder, because this drug has been shown to lower the seizure threshold. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. USE IN PREGNANCY: Safe use of desipramine hydrochloride during pregnancy and lactation has not been established; therefore, if it is to be given to pregnant patients, nursing mothers, or women of childbearing potential, the possible benefits must be weighed against the possible hazards to mother and child. Animal reproductive studies have been inconclusive. 4. USE IN CHILDREN: Norpramin (desipramine hydrochloride) is not recommended for use in children since safety and effectiveness in the pediatric age group have not been established. 5. The patient should be cautioned that this drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. 6. In patients who may use alcohol excessively, it should be borne in mind that the potentiation may increase the danger inherent in any suicide attempt or overdosage.

PRECAUTIONS: 1. It is important that this drug be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with this class of drug. Ordinary prudence requires that children not have access to this drug or to potent drugs of any kind; if possible this drug should be dispensed in containers with child-resistant safety closures. Storage of this drug in the home must be supervised responsibly. 2. If serious adverse effects occur, dosage should be reduced or treatment should be altered. 3. Norpramin (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates. 4. The drug may cause exacerbation of psychosis in schizophrenic patients. 5. Close supervision and careful adjustment of dosage are required when this drug is given concomitantly with anticholinergic or sympathomimetic drugs. 6. Patients should be warned that while taking this drug their response to alcoholic beverages may be exaggerated. 7. Clinical experience in the concurrent administration of ECT and antidepressant drugs is limited. Thus, if such treatment is essential, the possibility of increased risk relative to benefits should be considered. 8. The sedative effects of Norpramin and benzodiazepines (*e.g.*, chlordiazepoxide or diazepam) are additive. Both the sedative and anticholinergic effects of the major tranquilizers are additive to those of Norpramin. 9. This drug should be discontinued as soon as possible prior to elective surgery because of the possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients taking desipramine hydrochloride. 10. Both elevation and lowering of blood sugar levels have been reported. 11. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

ADVERSE REACTIONS: Note: Included in the following listing are a few adverse reactions that have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when Norpramin (desipramine hydrochloride) is given.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic: numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus.

Anticholinergic: dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis, increased intraocular pressure; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs.

Hematologic: bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue.

Endocrine: gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

DOSAGE AND ADMINISTRATION: Not recommended for use in children. Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients compared to hospitalized patients, who are closely supervised. Dosage should be initiated at a low level and increased according to clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a period of time and should be at the lowest dose that will maintain remission.

Usual Adult Dose: The usual adult dose is 100 to 200 mg. per day. In more severely ill patients, dosage may be further increased gradually to 300 mg./day if necessary. Dosages above 300 mg./day are not recommended.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response.

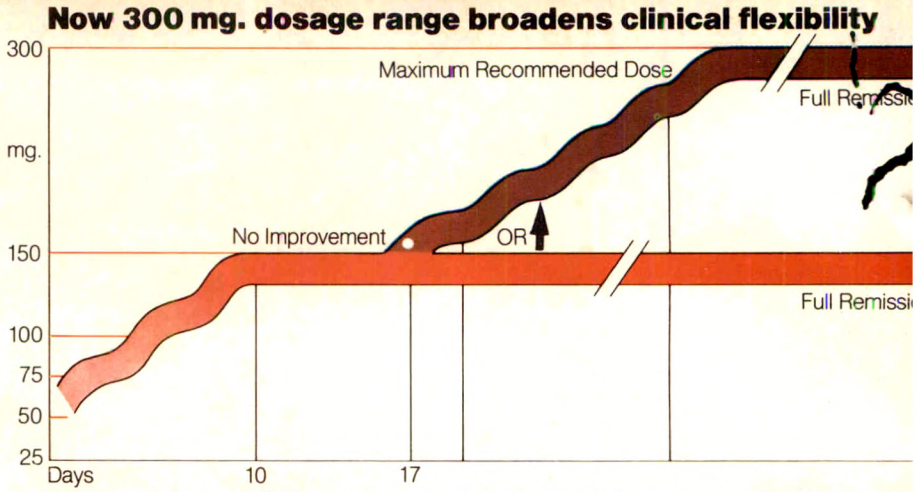
Treatment of patients requiring as much as 300 mg. should generally be initiated in hospitals, where regular visits by the physician, skilled nursing care, and frequent electrocardiograms (ECG's) are available.

The best available evidence of impending toxicity from very high doses of Norpramin is prolongation of the QRS or QT intervals on the ECG. Prolongation of the PR interval is also significant, but less closely correlated with plasma levels. Clinical symptoms of intolerance, especially drowsiness, dizziness, and postural hypotension, should also alert the physician to the need for reduction in dosage. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

Adolescent and Geriatric Dose: The usual adolescent and geriatric dose is 25 to 100 mg. daily.



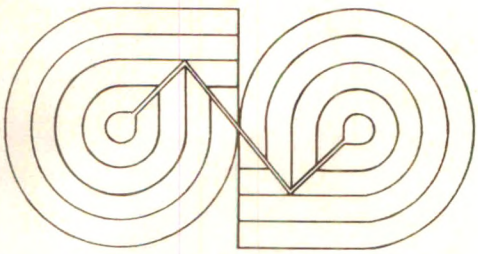
Dosage should be initiated at a lower level and increased according to tolerance and clinical response to a usual maximum of 100 mg. daily. In more severely ill patients, dosage may be further increased to 150 mg./day. Doses above 150 mg./day are not recommended in these age groups.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

OVERDOSAGE: See prescribing information for a discussion of symptoms and treatment of overdose.

Product Information as of April, 1978



A maximum dosage of 300 mg. a day, as a single or divided dose, may now be prescribed fo Norpramin. Since inadequate dosage is thought to be one of the major causes of treatment failure, the new therapeutic range should prove clinically helpful. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

PKSAP-III

PSYCHIATRIC KNOWLEDGE AND SKILLS SELF-ASSESSMENT PROGRAM

CONTINUOUS OFFERING

PKSAP-III is again available. The Program, initially available to physicians in Spring/Summer, 1977, will differ in that central scoring services will not be provided. Each registrant will receive the question booklets, the Reference guidebook containing the correct answers and bibliography, a score worksheet, and the Performance Data Report, which will facilitate self-scoring, follow-up reading and study at the participant's convenience. For further program details, the Bulletin of Information, is available upon request to the APA, Office of Education.

To register, remit the appropriate fee with this application form to the APA, PUBLICATIONS SALES. PLEASE MAKE CHECKS PAYABLE TO APA, PKSAP-III.

PKSAP-III REGISTRATION FORM — CONTINUOUS OFFERING

☐ Physician (other than above)	$50.00

Please make check payable to APA, PKSAP-III. Mail to: Publication Sales, APA, 1700 18th Street, N.W., Washington, D.C. 20009

SIXTH INTERNATIONAL GENDER DYSPHORIA SYMPOSIUM

The Departments of Reproductive Medicine and Psychiatry; Divisions of Urology and Plastic Surgery; and the Office of Continuing Education in the Health Sciences, University of California San Diego School of Medicine will sponsor the Sixth International Gender Dysphoria Symposium at the Hotel Del Coronado, Coronado, California, February 21-25, 1979. Presentations will be made in psychological, physical and endocrinologic diagnosis and management of Gender Dysphoria. This program is designed for the professional in the medical, social and psychological disciplines that evaluate the problems of patients with a variety of trans-gender states. Internationally renowned experts in the field will present invited papers. The course is designed to promote the widest possible audience participation and discussion of each paper, and the attendance is therefore limited. The proceedings of the symposium will be published. The symposium will be accredited by the American Medical Association, and the associations of the various disciplines involved. All professionals are invited to attend.

FOR REGISTRATION INFORMATION CONTACT:
Joseph F. Kennedy, M.D.
Program Chairman
6th International Gender Dysphoria Symposium

The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.

The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

a consideration beyond efficacy alone...

Infrequent akathisia and other disabling extrapyramidal effects...

The rapidly rising readmission rate among discharged psychotic patients is mainly due to noncompliance with antipsychotic drug therapy. And this, in turn, may be largely attributed to disabling extrapyramidal side effects, notably akathisia.[1]

Although extrapyramidal effects are characteristic of antipsychotic agents in general, with Mellaril (thioridazine) such effects are infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided. Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

Extrapyramidal Effects of Selected Antipsychotic Agents*[2]

DRUG	EXTRAPYRAMIDAL EFFECTS
Chlorpromazine	Moderate
Perphenazine	High
Prochlorperazine	High
Fluphenazine	High
Acetophenazine	Moderate
Trifluoperazine	High
Chlorprothixene	Moderate
Thiothixene	Moderate
Haloperidol	High
MELLARIL® (thioridazine)	Low

*Based on antipsychotic dosage ranges

Mellaril® [thioridazine]

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP
CONCENTRATE: 100 mg per ml

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.
Store and dispense Concentrate below 86°F; use tight, amber glass bottle. Just prior to administration, Concentrate may be diluted with distilled water, acidified tap water, or suitable juices; preparation and storage of bulk dilutions is not recommended.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.
It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

THE AMERICAN JOURNAL OF PSYCHIATRY

Genetic Counseling for Psychiatric Patients and Their Famili

BY MING T. TSUANG, M.D., PH.D.

The author presents an overview of genetic counseling for psychiatric patients and their families, including a brief summary of contemporary research into the evidence of genetic factors, the familial risks, and the possible modes of inheritance for major psychiatric disorders. The purpose is to review and condense the available literature pertaining to psychiatric genetic counseling for the benefit of psychiatrists and counselors in their day-to-day practice and for the general "consumer." It is hoped that giving the general public access to such information will help to reduce the suffering commonly brought about by the stigmatization of mental disorders.

"Is mental illness inherited?" Doctors are frequently asked such a question by concerned patients. Can the question be answered? No, not any more than one could say whether physical illness in general is inherited. Just as there are many kinds of physical illness, some inherited and some not, so there are many kinds of mental disorder, ranging from the most debilitating psychoses to states bordering on normality. Within the wide range of mental disorders, some, such as Huntington's chorea, have a clear genetic basis. Others, such as schizophrenia, affective disorder, and even alcoholism, have genetic components but also show the influences of environment. Still others, like the neuroses, are of uncertain cause y[illegible] volve a genetic predisposition, since th[illegible] tically run in families. "What pa[illegible] would you like to know about?" may [illegible] best reply.

This paper will present an overview o[illegible] seling for psychiatric disorders, inclu[illegible] of research findings in the genetics of [illegible] orders, which doctors may find useful [illegible] to patients or their families.

IS PSYCHIATRIC GENETIC COUNSE[illegible] LEGITIMATE?

Many professionals in the health scie[illegible] felt that psychiatric disorders are not [illegible] genetic counseling because of their unk[illegible] If we are not sure what gene defects [illegible] psychiatric disorders, how can we esti[illegible] any certainty?

This paper summarizes data from tw[illegible] adoption studies that give evidence of [illegible] for many of the major psychiatric illnes[illegible] knowing that there is a genetic basis for [illegible] substitute for knowing how the gene[illegible] works. However, some physical disea[illegible] logies that are no more certain than the [illegible] chiatric disorders are commonly the s[illegible] netic counseling.

Diabetes mellitus is a useful example [illegible] many parallels that can be drawn betwe[illegible] ophrenia, genetically speaking (1, 2). [illegible] and genetic factors appear to be at w[illegible] ease, but definite causes are unknown. [illegible] may in fact have several genetically [illegible] Neither disorder is likely to reveal itse[illegible] ly, each disorder has early onset form[illegible] be genetically distinct from its late on[illegible]

Such problems make counseling m[illegible] they do not preclude it. Doctors have [illegible]

practical means for estimating the risk of recurrence for ambiguously inherited disorders. Chiefly, they have access to pools of data from large epidemiologic studies that allow them to make reasonably accurate empirical risk estimates. Furthermore, advancements in genetics and statistical methodology have provided theoretical mathematical models into which many family data can be fit. Finally, doctors can serve patients and their families beyond offering risk estimates: they can dispel mistaken notions about psychiatric disorders, calm needless anxiety, and help those at risk to draw up a rational plan of action based on the best available information.

BENEFITS OF PSYCHIATRIC GENETIC COUNSELING

Misunderstandings of genetic disorders, mental illness, and genetic counseling can easily create certain anxieties that informed and humane psychiatric genetic counseling can do much to alleviate. In particular, counseling can correct the following common but mistaken beliefs:

1. If a disorder is genetic it inevitably occurs in those who possess the harmful genes. In psychiatric disorders especially, a 100% genetic influence is by far the exception rather than the rule. Genetic factors are variable, and environmental variables may play a role even when genetic factors are present. Only Huntington's chorea seems to obey strictly genetic rules. For other psychiatric disorders, the relationship between environmental and genetic influences is different in each case, and both types of factors have different impacts on different individuals. Some people may be carriers of damaging genes and yet experience no symptoms of the disorder themselves.

2. If a disorder is genetic it is untreatable. Even though some psychiatric disorders, such as dementia, often follow a continuously deteriorating course, other disorders frequently respond to treatment. For example, phenylketonuria, a rare genetic disorder that appears during the first year of life, can often be controlled by early supervision of the infant's diet. The course of manic-depressive disease can often be influenced positively by treatment with lithium carbonate (3, 4).

3. Genetic counseling is associated with eugenics and genocide. This belief, perhaps based on memories of the horrors of Nazi Germany, is unjustifiable. Contemporary genetic counseling is as removed from such atrocities in method and purpose as the peacetime nuclear reactor is from the atom bomb. Contemporary genetic counseling is noncoercive, stressing the autonomy of the individual in decision-making. Genetic counselors seek to distribute genetic information to those who request it and to aid counselees in forming their own resolutions based on the information they receive. Doctors will sometimes find it necessary to raise the level of anxiety in counselees who take the implications of mental illness too casually. At other times, the doctor may be able to relieve anxiety in the overly pessimistic patient or relative. Both functions serve the broadest purpose of genetic counseling: to reduce human suffering due to genetically transmitted disorders.

By correcting mistaken notions about genetic disorders and genetic counseling, the doctor may help counselees attain realistic estimates of the risks they confront. He or she may convince counselees to disregard the pseudo-scientific judgments of well-meaning relatives or friends and to reserve judgment until the diagnosis of the disorder is firmly established and the available facts are known. Some disorders may then call for careful family planning, while others may not raise such serious considerations.

The need for counseling for all genetic disorders is great because recent social changes and advancements in medical research have greatly increased the options for prospective parents who wish to circumvent the recurrence of serious genetic disorders. The public now has access to effective means of prenatal diagnosis, such as amniocentesis, which can detect chromosomal abnormalities or the sex of a child before birth. Effective means of contraception, sterilization, and legal abortion are available for those who wish to prevent high-risk births, and artificial insemination or adoption permits parents to bypass serious risk factors in building a family.

These developments have been popular subjects in the public media in recent years. Consequently, the public shows a new sophistication in scientific knowledge. Some may still be asking, "Is mental illness inherited?" while others may be inquiring whether they have a chromosomal aberration, and if so, what its origin is, whether it is transmissible, how it alters biochemical processes, whether it could be the result of drugs, or whether parental age is a factor in its transmission.

However, new knowledge can and often does create new confusions. Social and scientific developments offer power to the citizen to grant or prevent the creation of life, but new power brings concomitant responsibilities. When information is partially communicated or wrongly interpreted, it can bring about irresponsibility, prejudice, new forms of suffering, and greater legal, moral, and emotional burdens than ever before.

Here the contribution of the genetic counselor becomes plain. He becomes one of the arbitrators in the exercise of power. He has access to medical facts, probability models, gene frequency data, and empirical risk data. He has some idea of the course, outcome, and prognosis of a wide range of diseases. He has access to other medical, psychiatric, and legal specialists who can extend his expertise. He can calm, inform, encourage, advise. Equally important, he can withhold information where scientific uncertainties exist or where too much information would create confusion.

The psychiatric genetic counselor, as arbitrator, is a

catalyst in the prevention of suffering that results from severe genetically influenced mental disorders. He can interpret often puzzling and ambiguous developments in psychiatric research to genetically vulnerable families to help them make decisions about marriage or parenthood. At the same time he can inform those who need to know that some predictions can be made with reasonable accuracy on the basis of genetic evidence and that "not all mental illness is inherited."

WHO SEEKS PSYCHIATRIC GENETIC COUNSELING?

Three groups of people most typically seek professional advice concerning the genetics of psychiatric disorders: 1) psychiatric patients, 2) families of psychiatric patients, and 3) prospective spouses.

Patients usually seek counsel in the early stages of illness when they first become aware that the illness seriously affects their material prosperity, social adjustment, or family life. At that time they may be seriously concerned about the implications of the disorder for their descendants. In certain disorders that cause impairment of self-awareness, e.g., chronic deteriorating schizophrenia or late-stage Huntington's chorea, the patient is not likely to volunteer for genetic counseling. When self-awareness is retained to some degree—as in affective disorder, alcoholism, or neurosis—the patient is more likely to be counseled.

Families will most often approach a doctor for counseling when many incidences of illness have occurred among blood relatives or when there have been a few relatives with particularly severe or chronic mental illnesses. In cases of affective disorder, patients and their families are often counseled together. By the time a family seeks genetic counseling, it may already have experienced a remarkable degree of psychosocial and financial distress due to the presence of illness.

A prospective spouse will often seek counseling when psychiatric illness has become apparent in one or many of the partner's relatives. The prospective spouse may then want counsel concerning the genetic prospects for both the future partner and their potential offspring. The advice of the genetic counselor at this stage may indirectly serve an important, even crucial, function as marriage counsel.

THE STAGES OF COUNSELING

Genetic counseling may be defined as the process of communicating information and advice to patients and/or their relatives to help them deal with problems connected with the occurrence or possibility of recurrence of a genetically caused or influenced disorder. Various schematizations of this process can be found in the literature of genetic counseling (5–8), but genetic counseling usually includes seven basic stages, described below.

Diagnosis

The first step in the process must be ... agnosis of the disorder. This implies ob... cross-sectional picture based on the tota... sentation and a longitudinal view based ... clinical course, in addition to a comple... tory. Counseling under a mistaken d... more dangerous than counseling without ... the hereditary mechanism at work.

The standard diagnostic manual curre... the United States is the 2nd edition of th... *and Statistical Manual of Mental Disord...* published by the American Psychiatric A... 1968 (9). Because certain ambiguities of ... peared in *DSM-II*, APA is now revising ... and will soon publish *DSM-III*. For resea... more strictly defined criteria are available ... though these do not cover all diagnostic ... mental disorders. The physician must ... available means to make sure a disorder ... diagnosed before undertaking counsel...

A number of factors may complicate t... obtaining an accurate diagnosis, especial... ric disorders. Diagnostic criteria may dif... to clinic or from region to region. Furthe... cal expertise required to obtain an accu... may not be located within easy reach of t... Certain disorders that look alike may actu... ogeneous. Sometimes, purely enviro... can cause illnesses that closely resemble ... influenced disorders. Other disorders ... cally related but have no apparent rese... cause of variable ages of onset, idios... course, "variable expressivity," etc. In ... difficulties, the importance of obtaining a ... agnosis before proceeding with counseli... overemphasized.

Family History

The second stage of counseling involves ... a complete and accurate pedigree. If the ... still uncertain at this stage, the family his... veal the most probable one. It may also ... mode of inheritance of the disease. The fa... includes such information as parental age, ... ground, occurrence of abortions, stillbirths, ... deaths, as well as the ages, sexes, and hea... siblings and children. Primary attention is g... occurrence of the disorder in first-degree ... the family history also records the hea... blood relatives, such as grandparents, un... and cousins.

Risk of Recurrence

After the pedigree has been carefully ... physician must estimate, if possible, the ris... rence of the disorder. Risk refers to the ... that a given trait or disorder will occur in ... of an affected person. Murphy and Chase ...

guished three categories of information that can be used to arrive at an estimate of risk.

1. "Empirical information" consists of estimates based on data collected in controlled research. Such studies may provide the counselor with information about the rate of certain gene mutations in the population, the average age of onset of a disorder, or the estimated risk of recurrence in first-degree relatives (parents, siblings, children).

2. "Modular information" is based on a rational understanding of the mode of inheritance of a certain trait. Thus, while empirical information allows one to reason backward from known estimates to possible genetic factors, modular information permits more precise estimates based on known or reasonably certain genetic factors.

3. "Particular information" is all of the data contained in the family history of the person or persons whose genes are in question. This category is further divided into "posterior information" (i.e., information about all persons whose genetic makeup could be influenced by the person in question, such as children, grandchildren, etc.) and "anterior information" (i.e., all information on members of the pedigree who could not possibly have been influenced by the patient's genotype, such as parents, uncles, nieces, stepsons, etc.). Using such information, the doctor may be able to calculate "exact" risk, when the mode of inheritance and other crucial factors are known, or "empirical" risk, when the estimates must be based on average frequencies of a given disease among various degrees of relatives of people known to have the disease.

Evaluation of the Counselee

Before the doctor can effectively communicate the risk estimates to counselees and help them weigh the risk against the potential burden of the disorder, he or she must understand their intentions, intellectual capabilities, and states of mind. Do they seek information, advice, or both? Do they want advice for their own offspring or someone else's? How sophisticated is their acquaintance with genetic facts and principles? What is their general level of intellect? Can they make rational decisions? What is their present emotional state? Finally, how do they perceive the risk/burden ratio in their situation? Humane counseling must accommodate the specialized knowledge of the physician to the needs, intentions, personalities, and mental states of the counselees.

The Risk/Burden Ratio

The doctor must next help the counselees to weigh the estimated risk of recurrence against the burden of the disorder, even though they may tend to be concerned only with burden. Although risk can often be calculated with reasonable accuracy, there is no precise way to estimate burden. Burden is the expected cost to a family of a recurrence of disorder. It must be reckoned not only in terms of financial loss but also in terms of human effort, pain, loss of life, embarrassment, childlessness, grief, and many other intangibles (8).

Obviously, burden will be considered relatively low when the disorder is so severe that it is rapidly fatal or when it is long-lasting but does little to impair normal functioning over the course of a lifetime. The burden will be greatest when an individual suffers from severe impairment requiring elaborate supervision over a long period of time. Frequently, parents will take high risks if they perceive that the burden will be low but will "play safe" when the perceived burden is very great.

Forming a Plan of Action

Once the risk/burden ratio is understood, the doctor's responsibility is to assist counselees in forming a reasonable plan of action for deciding among their options. If the decision involves family planning, the decision whether or not to have children cannot and should not be made by the doctor. The decision properly belongs to parents themselves. However, the doctor's role must go beyond mere stating of facts. He is better able than the parents to predict consequences, but he should do so with care. He may also explain his own preferences for certain courses of action. Finally, however, he must commit all responsibility for the decision to the parents, without pressuring or rushing them.

This stage of counseling requires that the physician assess the counselees' understanding of what they have been told. He may ask them to repeat to him what they understand, or he may summarize in writing the main points that arose during the counseling session.

Follow-Up

The final stage of genetic counseling must be follow-up. Follow-up within a reasonable period of time permits continued assessment of the counselees' understanding. It may also provide new data leading to a more exact prognosis, e.g., a subsequent birth or other follow-up information may specifically indicate a certain mode of inheritance. Such information may permit a revision of the risk estimates for greater accuracy.

METHODOLOGY IN PSYCHIATRIC GENETIC STUDIES

The most effective means for studying the presence of genetic factors in psychiatric disorders, in increasing order of precision, are family, twin, and adoption studies. These are the most widely published studies; however, recent advances in medical and genetic technology have also led to research on linkage or association between some disorders and known genetic markers (12–15). The finding of association between certain genes and certain disorders could provide practical means to determine the presence of genetic predispositions for those disorders. The finding of linked genes could implicate a major gene to the exclusion of

a polygenic mode of inheritance. However, since the evidence is inconclusive at present, I will not go into further detail concerning linkage and association.

Family and Twin Studies

Family studies are useful in providing reasonable risk estimates for various disorders among different classes of relatives of affected patients. They may suggest the presence of genetic factors by showing the concentration of various illnesses within families, but genetic factors cannot be distinguished from environmental ones on the basis of family studies.

Twin studies involve a comparison of two types of twin pairs: monozygotic (MZ) and dizygotic (DZ). Monozygotic twins can be expected to be 100% genetically identical, whereas dizygotic twins can be expected to be about 50% genetically identical, like other siblings. Since MZ twins have identical genes, any differences between them must be due to nongenetic factors. On the other hand, it cannot be assumed that all similarity between twin partners (their "concordance" for a given condition) is due only to genetic factors. Their similarities may also result from a largely identical environment.

Twin studies attempt to test whether genetic factors are present for certain conditions by comparing the MZ twin concordance rate for a given condition with the DZ concordance rate for the same condition. Environmental effects are assumed to be approximately equal for the two types of twins. Thus, in a representative sample of twins, if the MZ concordance rate is significantly higher than the DZ concordance rate, there is strong evidence that the condition in question has been influenced by genetic factors, although the twin study cannot completely disentangle genetic from environmental influences.

Adoption Studies

Adoption studies achieve the best results in distinguishing genetic from environmental influences. They study persons who were separated from their biological parents at birth and raised with biologically unrelated adoptive parents. By controlling for the environmental factor in this way, one can separate the interacting influences of genes and environment in the causation of given disorders. If the adoptee is significantly more like his biological relatives than his adoptive relatives, a genetic factor is assumed to be present. Adoption studies have four basic designs: 1) the adoptee study design, 2) the adoptees' parents study design, 3) the adoptees' family study design, and 4) the "crossfostering" design (16).

The adoptee study investigates the rate of disorder in the adopted-away children of ill parents. The adoptees' parents and family studies investigate the rate of disorder in the parents and relatives, respectively, of ill adoptees. The crossfostering study investigates the rate of disorder in children born to normal parents but raised in the homes of disordered adoptive parents. Occasionally adoption and twin studies are combined in an investigation of MZ [illegible] raised apart.

GENETIC FACTORS IN SPECIFIC PSY[illegible] DISORDERS

This section offers a brief outline of e[illegible] presence of genetic factors in several m[illegible] ric disorders. Because of space limitatio[illegible] attempted to mention all pertinent rese[illegible] scribe any one study in full detail, althoug[illegible] extensive literature has been weighed in [illegible] sults germane to this discussion.

Schizophrenia

Twin study data from investigations [illegible] ferent countries have shown that MZ tw[illegible] significantly higher concordance rates fo[illegible] nia than DZ twin pairs (MZ pooled rate [illegible] pooled rate=13.7%) (17). These studies [illegible] that as the genetic relationship between w[illegible] more similar—from opposite-sex DZ to [illegible] to MZ—the intrapair concordance rises [illegible] (18). The fact that even MZ concordance [illegible] than 50% suggests that environmental [illegible] netic factors play a significant role in the [illegible] of schizophrenia.

Adoptee studies have shown signifi[illegible] rates not only of schizophrenia but also o[illegible] psychiatric disorders (e.g., personality d[illegible] social personality, and mental deficiency) [illegible] away children of schizophrenics than [illegible] adoptees (19, 20).

Several adoptees' family studies have fou[illegible] cantly higher rates of schizophrenia among bi[illegible] cal relatives of schizophrenic adoptees than [illegible] ther their adoptive families or the biological [illegible] tive families of controls (21, 22). These studies [illegible] twin study evidence in showing the presence o[illegible] factors in schizophrenia. A crossfostering [illegible] adoptees raised by schizophrenic parents fou[illegible] 4.8% rate of schizophrenia compared with [illegible] cantly higher rate (19.7%) among adopted-a[illegible] spring of schizophrenic biological parents (2[illegible] finding suggests that schizophrenia in a par[illegible] not promote the development of schizophren[illegible] child if the child is not genetically predisp[illegible] schizophrenia.

Affective Disorder

A pool of seven major twin studies (see refere[illegible] for a summary) shows an overall MZ twin concor[illegible] rate of 76% for affective disorder, compared w[illegible] overall rate of 19% for DZ twins. Studies of MZ [illegible] reared apart (25) show a 67% concordance rate, [illegible] is statistically similar to the overall concordan[illegible] MZ twins. Twin studies of affective disorders [illegible] been summarized by Gershon and associates (26

significant difference between MZ and DZ concordance rates indicates a strong genetic factor in affective disorder.

Mendlewicz and Rainer (27) recently conducted a study of adoptees' parents in Belgium that strongly supports twin studies in showing the importance of genetic factors in affective disorders. When the biological and adoptive parents of 29 bipolar adoptees were compared, the former showed significantly higher rates for all psychopathology (40% versus 16%), particularly affective disorders. Further, the rate of affective disorders in these biological parents (31%) was not statistically different from the rate of affective disorders among parents of 37 bipolar nonadoptees (26%). This study, in which a rigorous research design was used to control for environmental factors, offers strong support for previous studies implicating genetic factors in bipolar illness. A very recent adoptee study (28) also reported a significantly increased incidence of depression in adoptees who had affectively disordered biological parents.

Presenile Dementias

From a counseling perspective the most important of the dementias are the presenile dementias—Huntington's chorea, Alzheimer's disease, and Pick's disease. Because these are slowly deteriorative conditions with usual onset in middle age, they impose a greater overall burden than forms with later onset, such as senile dementia. Usually, the genes are transmitted to offspring before the disease manifests itself in the parents. Family studies of Huntington's chorea show a clear pattern of autosomal dominant inheritance with age-dependent penetrance. Some kindreds in which Alzheimer's and Pick's diseases appear also show autosomal dominant inheritance, but most cases of these illnesses are of uncertain heredity (29).

Alcoholism

Although environmental factors are very important in alcoholism, twin and adoption studies have shown that genetic factors also seem to be present (30, 31). A well-designed twin study by Kaij (32) examined concordance according to the severity of alcohol abuse. In the two categories of greatest severity, DZ twins showed a high concordance rate (66.7%), but MZ concordance rates were significantly higher (84.5%) (32). In the same study, concordance for alcohol abuse increased with increasing severity of abuse in MZ but not in DZ pairs. These findings give evidence of genetic factors in alcoholism. However, major adoption studies of alcoholism have supported genetic influence only in the case of male adoptees. A Danish adoptee study of alcoholism (33, 34) found a significantly higher rate of alcoholism among the adopted-away sons of alcoholic biological fathers than among control adoptees. Adopted-away daughters of alcoholic biological fathers show no higher rates of alcoholic abuse than control adoptees (35).

Sociopathy

Sociopathy by definition involves environmental factors, but twin and adoptive studies suggest the presence of genetic factors as well (36, 37). Twin studies of psychopathy (38, 39) show MZ concordance rates ranging from 36% to 100% and DZ concordance rates of up to 54%. These high rates point strongly toward the existence of both genetic and environmental factors in sociopathy.

An adoptee study found a rate of 13% for antisocial personality among the adopted-away offspring of female legal offenders compared with a base rate for antisocial personality among all adoptees of about 2.3% (40). A recent adoptee study of antisocial behavior by Cadoret (37) found a significant correlation between the diagnosis of antisocial personality or behavior in an adoptee and the same diagnosis in a biological parent. Both studies used the adoptee design to control for environmental influences and suggest that genetic factors are present in antisocial personality.

Neuroses

Certain types of personalities seem more prone than others to anxiety in response to environmental stress. It is supposed, therefore, that the many, many genes which regulate the processes of personality development and physiological response, although their individual effect is small, may have a combined influence in creating a predisposition to neurosis in some people. Evidence for such an influence has been provided by twin studies, which have generally found much higher concordance rates for neurosis among MZ than DZ twin pairs. A major study of neurosis and personality disorder in 146 twin pairs by Slater and Shields (41) found that in 47% of the MZ pairs both members received a psychiatric diagnosis compared with only 24% in DZ pairs. The same diagnosis was given to both members in 29% of the MZ pairs but only 4% of the DZ pairs. The ratios between MZ and DZ concordance rates in the study suggested that genetic influence was specific to anxiety neurosis and personality disorder, in marked contrast to reactive depressions and other forms of neurosis (41, 42).

RISK ESTIMATES FOR SPECIFIC PSYCHIATRIC DISORDERS

Except in the case of Huntington's chorea, where the genetic mechanism is known, doctors must rely on empirical data to calculate risk estimates for various psychiatric disorders. The doctor must distinguish between exact estimates, based on known genetic mechanisms, and empirical estimates, based on observed frequencies of disorder, using the latter only when they would clearly be of benefit to patients or their relatives.

Empirical risk estimates are established through family studies, which investigate the frequency of dis-

TABLE 1
Morbidity Risk of Schizophrenia*

Relatives of Schizophrenics	Risk (%)
First-degree	
Parents	4.4
Siblings	8.5
Neither parent schizophrenic	8.2
One parent schizophrenic	13.8
Children	12.3
Both parents schizophrenic	36.6
Second-degree	
Uncles and aunts	2.0
Nephews and nieces	2.2
Grandchildren	2.8
Half-siblings	3.2
Third-degree	
First cousins	2.9
General population**	0.86

Based on Slater and Cowie (44); data mainly derived from pooled data of Zerbin-Rüdin (43), with only cases of definite schizophrenia counted.
Compiled from 19 investigations in six countries (43).

orders among various classes of relatives. When risk estimates among relatives of affected patients are higher than the general population risk for a given disorder and when risk estimates are higher among near relatives than among distant relatives, risk figures offer suggestive but not conclusive evidence for genetic factors in a given disorder.

Empirical estimates must be viewed with caution, since many factors may call their accuracy or usefulness into question. Observed frequencies may be based on epidemiologic studies that contain sampling biases. Various studies offer widely differing estimates that may reflect cultural differences. Finally, the empirical risk estimate may be irrelevant or even misleading. It would be a disservice, for instance, to quote an empirical risk figure of 15% to a patient whose family history for a given disorder shows dominant inheritance with complete penetrance that would set the exact risk for siblings and offspring at 50%, as could be the case in Alzheimer's or Pick's disease.

The following is a brief summary of available risk data for specific psychiatric disorders.

Schizophrenia

Risk figures pooled from numerous studies (43, 44) are presented in table 1. The general population risk, compiled from 19 investigations in 6 countries, is 0.86%. The risk rates among first-degree relatives of schizophrenics are roughly 10 times the general population risk and nearly 3 times the risk for more distant relatives. Since most of these data are drawn from classical European studies, they reflect empirical risk estimates for process schizophrenia, the usually severe, deteriorating form of the disorder. If milder syndromes such as borderline, acute, latent, or schizo-affective schizophrenia were included in the criteria; as is more commonly done by investigators in the United States, the total number of schizophrenics diagnosed would be much greater, and risk estimates would be different from those in table 1. Unfortu[illegible] risk estimates for relatives of borderl[illegible] ics have not yet been obtained becaus[illegible] the current definition of borderline sc[illegible]

Affective Disorder

The age-adjusted risk for manic-d[illegible] sis in the general population is 1.[illegible] 2.5% for females, as estimated in a[illegible] lation study (45). Other studies hav[illegible] rates among first-degree relatives o[illegible] fective disorder of approximately 10.5[illegible] (46). The higher risk figures reflect [illegible] containing only cases of bipolar a[illegible] Winokur and Clayton (47) have estima[illegible] for siblings of an affected person [illegible] when one parent is affected, and wh[illegible] fected the risk rises to 43%.

Presenile Dementia

Since Huntington's chorea is trans[illegible] autosomal dominant gene with age-dep[illegible] trance, the unmodified risk to siblings [illegible] affected patients is 50%. Beginning fr[illegible] counselor can estimate the probability [illegible] will develop the illness at a given age [illegible] onset can be considered normally dist[illegible] the person passes through the age of ris[illegible] veloping the illness, the risk estimates [illegible] ly lowered on the basis of reasonably a[illegible] onset data.

It is estimated that the general po[illegible] Alzheimer's and Pick's diseases toget[illegible] mately 0.1% (48). For parents of affec[illegible] risk is 15%; for all siblings, the rate is 5% [illegible] least one parent is affected, 2.5% whe[illegible] is affected). For those families in which [illegible] dominant pattern of inheritance appea[illegible] quite clear: 50% for the siblings and off[illegible] fected cases and 25% for their second-deg[illegible] (nieces, nephews, grandchildren).

Alcoholism

A survey of studies in five different cou[illegible] ed risk rates for alcoholism in the general [illegible] 3%–5% for males and 0.1%–1% for fem[illegible] higher rate for males is consistent in studi[illegible] ism and is seen again in the risk estimates [illegible] of alcoholics. Data from six studies of chr[illegible] ics show risk figures of 0.4%–8.2% for mot[illegible] holics and 2.8%–10.3% for sisters. The ris[illegible] relatives are roughly 5 times higher than [illegible] males—11.4%–32.6% for fathers of alco[illegible] 12.2%–27.7% for brothers (1). A study [illegible] and associates (49), which used personal [illegible] with family members to ascertain familial [illegible] coholism, found even higher rates amon[illegible] lings—46% for brothers of male alcoholics [illegible] sisters of male alcoholics. The brothers of fe[illegible]

holics also had a high risk rate of 50%, while the rate for sisters of female alcoholics was only 8%.

Neurosis

A few family studies of anxiety neuroses have shown that the risk to parents and siblings of an affected person is approximately 15% (44).

HOW ARE SPECIFIC PSYCHIATRIC DISORDERS INHERITED?

Doctors would benefit greatly from having clear modular information that would permit them to replace empirical risk figures with more exact risk estimates for specifically diagnosed disorders. Unfortunately, the modes of inheritance for most major psychiatric disorders are not yet clearly understood. In this state of uncertainty, researchers have interpreted the available data to formulate theories about the possible genetic modes of transmission for many disorders. The complex arguments for and against such theories are beyond the scope of this discussion. Instead, I will present a brief outline of genetic models that have been proposed for certain major psychiatric disorders. Definitions and more complete discussions of basic genetic principles can be found in numerous textbooks on human genetics and genetic counseling (1, 5, 8, 50).

Schizophrenia

Theoretical models for the inheritance of schizophrenia may be grouped in three classes (51–53): monogenic, polygenic, and genetic heterogeneity.

Monogenic models in general postulate a single specific schizophrenic gene that may cause the disease to be manifested either in homozygotes only or in both homozygotes and heterozygotes (54–61). A recessive gene model is not widely advocated. Most monogenic models posit a dominant gene with a modified effect. The modification may result from other genes at other loci, from reduced penetrance (penetrance rates have been estimated at 6%–13%), or from intermediate effects, where schizophrenia is manifested in 100% of homozygotes but only in about 25% of heterozygotes. Polygenic theories include both "continuous phenotypic variation" and "quasi-continuous variation" models (51, 62–66). Both single-dominant-gene theories and polygenic theories fit the available data well enough that for practical purposes the doctor may adopt the one that best suits his or her purposes in counseling (44).

Genetic heterogeneity theories propose that schizophrenia is not a single disease entity but a variety of diseases that probably have different etiologies and modes of transmission (67). Schizophrenia may first be divided into organic (symptomatic) and idiopathic (true) categories. The former involves a clear precipitating factor such as brain damage or drug abuse, and the latter involves no clearly precipitating factors and shows a different pattern of clinical symptoms and family history. Idiopathic schizophrenia may be further divided into typical and atypical (68–70). Within typical schizophrenia, clinical and family differences may point to a distinction between paranoid and nonparanoid types (71–73). Within nonparanoid schizophrenia, a distinction between simple, catatonic, and hebephrenic subtypes may be possible (74). Within atypical schizophrenia, it may be possible to distinguish an affective type, a schizophrenic type, and an undifferentiated type (75). Some cases of schizophrenia, it has been postulated, may be due to rare genes that are specific for the individual subtypes of schizophrenia (68).

Affective Disorder

The exact mode of transmission for affective disorder is not yet known, but several genetic theories have been proposed, chiefly genetic heterogeneity, X-linked dominant, autosomal dominant, and polygenic models.

Numerous studies have suggested that bipolar affective disorder is genetically distinct from unipolar depression (47, 76, 77). Other studies have offered additional evidence for a bipolar-unipolar distinction by showing that bipolar patients as a group respond better to treatment with lithium carbonate than unipolar patients (3, 4). Some studies suggest that unipolar depression itself may be comprised of two genetically distinct types: 1) depressive spectrum disease, which occurs mostly in females under 40 years, and 2) pure depressive disease, which occurs mostly in males over age 40 (78). This hypothesis is not yet sufficiently tested to warrant general acceptance.

Many studies (12, 14, 79), including the recent adoption study by Mendlewicz and Rainer (27), have found evidence for an X-linked mode of transmission for bipolar affective disorders. The evidence for linkage is usually an absence of ill father-ill son pairs. Additional support for the hypothesis has come from studies linking bipolar affective disorder with known genetic markers such as color-blindness and the X_g^a blood group. However, numerous studies have contradicted an X-linked hypothesis by finding ill father-ill son pairs (13, 76, 80–86). Information on X-linkage is not very useful for counselees, since it is not yet possible to determine clinically which cases of bipolar affective disorder are sex-linked. Until the question of X-linkage is resolved, doctors should not counsel as though bipolar affective disorder were a sex-linked disorder, since doing so might result in a serious counseling error.

Other genetic theories for the transmission of affective disorder have invoked either a single autosomal dominant gene of approximately 30% penetrance (77, 81, 82) or a polygenic model with quasi-continuous variation (57, 87–89). Certain statistical techniques such as threshold model analysis (90, 91) and segregation analysis (92) have recently been devised for the purpose of determining whether single major genes or groups of genes are responsible for genetic transmis-

sion. However, conclusive results have not yet been obtained using such models.

Presenile Dementia

The genetic mechanism in Huntington's chorea has already been discussed. Autosomal dominant kindreds also appear in a small minority of cases of Pick's and Alzheimer's diseases (29, 93). In families where an autosomal dominant gene is not implicated for Pick's and Alzheimer's disease, the inheritance appears to be polygenic, but the exact mode is not certain (48).

Alcoholism

The predominance of males in all samples of alcoholics leads naturally to the suspicion of X-linked recessive transmission for alcoholism. If alcoholism were X-linked, it might be expected that the sons of daughters of alcoholics would show a higher incidence of alcoholism than the sons of the sons of alcoholics. However, a study specifically designed to test this hypothesis found no evidence to support it (94). In the study, the risk of alcoholism for all grandchildren of alcoholics was 43%. Such findings do not fit recessive gene models but could be interpreted as fitting a dominant gene model.

Sociopathy

All major adoption studies of sociopathy point to the influence of both environmental and genetic factors in the transmission of antisocial personality, criminality, and psychopathy (95–97). Data from a St. Louis family study of sociopathy fit a multifactorial model of disease transmission well enough to suggest that the model may be acceptable as a description of the mode of inheritance in sociopathy (98). However, the relative importance of genetic and environmental factors in sociopathy is not yet clearly understood. The same researchers have found evidence in family study data to suggest an overlap between sociopathy and Briquet's syndrome (hysteria), indicating that the two may be manifestations of a single process rather than independent disorders (99). Chromosomal abnormalities have been implicated in some studies of criminality. Males with an extra X chromosome (Klinefelter's syndrome) or an extra Y chromosome seem to be at almost 20 times the normal risk for incarceration, although the chromosomal abnormality itself cannot at present be proven responsible for the increased risk (100).

CONCLUSIONS

I have discussed the psychiatric disorders for which genetic counseling is most commonly sought, the evidence for genetic factors in each, risk rates based on empirical data, and possible modes of inheritance. Many other psychiatric disorders are known, but an account of all of them lies outside the scope of this paper. For further information, the reader is referred to standard textbooks on human genet[illegible] counseling (5, 44, 50). Many forms of [illegible] tion show autosomal dominant, autosom[illegible] or X-linked patterns of transmission. Ty[illegible] other psychiatric disorders that may fo[illegible] models, have been usefully catalogu[illegible] (101).

The Incidence of Psychosurgery in the United States, 1971–1973

BY JOHN DONNELLY, M.D.

As part of the work of the APA Task Force on Psychosurgery, the author surveyed 1,901 neurosurgeons on how many psychosurgical procedures they performed in 1971, 1972, and 1973. A total of 1,481 questionnaires were returned; 195 neurosurgeons indicated they had performed a total of 476 procedures for intractable pain and 1,039 procedures for psychiatric conditions. Excluding the procedures reported by 4 neurosurgeons who performed more than 20 psychosurgical operations in any one of the three years, the number of psychosurgical operations is 575 for the three years, which the author suggests should allay fears about the abuse of psychosurgery.

IN THE POLITICAL TURMOIL during the decade of the troubles in the cities and of the Viet Nam war, the then somewhat obscure and declining use of neurosurgical treatment of psychiatric disorders was elevated to a position, one might say, of social prominence. Activist psychiatrists and others made repeated and highly publicized accusations that perhaps thousands of individuals were being subjected to such operations needlessly and for purely experimental purposes, as well as for political, social control, racist, and other reasons. Psychosurgery became a torch of activist psychiatrists in the United States.

In the emotional ferment of those times, the scientific value of objective evaluation was typically absent in the hierarchy of priorities of many psychiatrists, whether activist or not. It became fashionable, indeed *de rigueur*, for even nonactivists to issue statements disclaiming any support for its use—and incidentally implying opposition to it.

Within the American Psychiatric Association itself, the issue of psychosurgery became for activists a *cause célèbre*. In 1973 the Task Force on Psychosurgery was established under the aegis of the Council on Emerging Issues to study all aspects of the subject and to submit its findings and recommendations regarding the use of psychosurgery. In October 1976 the task force report was submitted to the APA Board of Trustees, who decided to refer the report back to the Council on Emerging Issues—without recommendation.

SURVEY OF PSYCHOSURGERY

As part of the work of the Task Force on Psychosurgery, the author undertook a survey of the use of neurological surgery for the treatment of psychiatric conditions by neurosurgeons in the United States. A search of the literature revealed only one recent study of the extent to which psychosurgery was performed, but this drew only a 31.5% response from the neurosurgeons surveyed (1).

In constructing the survey questionnaire, a number of difficult decisions were necessary. The first was how to keep the questionnaire as simple as possible and demand relatively little work from the recipients in order to obtain as great and as accurate a response as possible.

A significant question also arose immediately with respect to the inclusion of intractable pain as a psychiatric condition; surgery for this condition is not regarded as psychosurgery by neurosurgeons, especially when the pain is caused by conditions such as malignancies. Yet in some cases intractable pain cannot be demonstrated to be due to physical diseases and is known to occur as a psychogenically determined symptom.

Another problem was that most of the publicized charges repeatedly referred to "lobotomy." This particular technique, the procedure used when psychosurgery was introduced in 1939, has long been superseded by methods more accurate and more limited in their destruction of brain tissue. It was desirable, therefore, to obtain a picture of current procedures, of the specific conditions for which psychosurgery is performed, etc.

The one-page questionnaire (appendix 1) was numbered so that the returns could be followed up. Respondents were given the option of not signing their names, and all were promised that their identity would be kept completely secret. A very large number did, however, sign the form.

METHOD

Questionnaires, which covered the years 1971, 1972, and 1973, were sent on December 31, 1973, to all sen-

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2–6, 1977.

ior and active U.S. and Canadian members (N=1,450) on the 1973 membership list of the American Association of Neurological Surgeons. The Congress of Neurological Surgeons furnished the mailing list of its members, and questionnaires were sent to those who were not also on the membership list of the AANS (N=451). In response to this combined mailing 1,065 replies were received.

On April 30, 1974, 837 questionnaires were again sent to the neurosurgeons who had not responded. From this mailing 416 returns were received, so that out of the 1,901 neurosurgeons contacted 1,481 replied and from 420 there was still no response.

In order to ascertain where psychosurgery was carried out, every member hospital of the National Association of Private Psychiatric Hospitals was sent a questionnaire. Of the 151 hospitals involved, 139 replied. Of the 12 not responding, on examination of the size, type of patient served, and reputation, it was judged that no psychosurgery would have been conducted in this group of hospitals.

Consideration was given to sending questionnaires to community general hospitals, state hospitals, Veterans Administration hospitals, etc., but it was concluded that the responses were most likely to be sparse and the statistics derived not significant enough to reach any valid conclusions.

RESULTS

There was a 78% rate of return, an exceptionally high percentage for a questionnaire study, which probably reflects the degree of neurosurgeons' interest in a controversial issue involving their special area of professional concern. Of the 1,481 questionnaires that were returned, 18 were returned by the postal service as unforwardable and 35 had been sent to neurosurgeons who were retired or deceased; 1,231 neurosurgeons indicated that they had not performed surgery for the treatment of psychiatric disorders. Of the 197 who had, 2 responses were eliminated, the first because the number of procedures was not listed and the second because the 7 operations reported had been performed outside North America. The breakdown of the remaining 195 responses is shown

Analysis of the responses indicating for both intractable pain and psych demonstrated that they could be su sets. The first set included 23 response number of procedures performed for and those for the treatment of psychi The second set was composed of 19 re tained additional information so that ment could be exercised in allocating for intractable pain and those for ps making this allocation, considerato comments noted on the questionnai surgical procedures reported, and treated, etc. The numbers arrived at sion to assign to psychosurgery rathe for intractable pain those procedu purpose was uncertain.

The third set, which presented great cluded the returns from 10 neurosurge was not possible to distinguish specif cedures for pain from those for psych In order to avoid the charge of bias r surgery, all such returns, covering were placed in the psychosurgery cat doubtedly true that this group, the e least a significant number of procedure conditions other than psychiatric.

Of the 110 neurosurgeons in the Ju performed psychosurgery in 1971, 19 specified having performed a total of the 635 procedures performed by the o ther determined to be psychosurgery o as such, yielding a total of 972 proce year. There were 18 Canadian neu specified having done a total of 61 psy cedures and 1 whose 6 procedures were total of 67 procedures or 23 per year.

A total of 420 questionnaires were n though the reasons may vary, it is like jority of nonrespondents had little inte surgery. Nevertheless, assuming the s formance by them as by the respondent 276 procedures would give a correcte operations. Because only a handful of

were Canadians, the corrected number was allocated to neurosurgeons in the United States, yielding a total of 1,248 procedures or 416 psychosurgical operations per year in the United States.

It may be of interest to compare the incidence of psychosurgery in the United States and Canada with that in other countries. According to the report of the National Commission on the Protection of Human Subjects of Biomedical and Behavioral Research (2), it is estimated that between 200 and 250 such operations were performed annually between 1973 and 1975 in the United Kingdom and approximately 83 in Australia. Based on population, the rate in the United States is half that in the United Kingdom and one-third that in Australia.

For a variety of reasons, including accusations that had been leveled about the abuse of psychosurgery, but more specifically to determine the distribution of psychosurgery, the frequency of operations by individual neurosurgeons was obtained by a breakdown of the number of procedures by year (table 2). The total of the numbers of neurosurgeons, of course, includes some operating in one, two, or three years or any combination of years. It is extremely interesting to note that a relatively small proportion of the neurosurgeons responding reported having carried out psychosurgical procedures in all three years.

Also of interest are the figures resulting from removing just 4 neurosurgeons who carried out more than 20 procedures in any one of the three years. In 1971 72 neurosurgeons in the United States performed 198 procedures, in 1972 68 performed 210 procedures, and in 1973 57 carried out 167 psychosurgical procedures, yielding a total of 575 psychosurgical operations carried out by those U.S. neurosurgeons who performed fewer than 20 procedures in any one of the three years. It will be noted that there was a decline in 1973 in the number of neurosurgeons and of the procedures they performed. This decline from 1971 to 1973 was, without doubt, the consequence of the notoriety that was generated by adverse publicity regarding psychosurgery.

The statistics on psychosurgical procedures performed by individual neurosurgeons are of interest because the question has been raised whether infrequency of operation is related to proficiency and to results. On the other hand, it has been argued that increased frequency is related to lack of discriminating selection of patients. Of the U.S. neurosurgeons who performed psychosurgery in 1971, 1972, and 1973, there were 62, 55, and 49 neurosurgeons in the respective years who performed 4 or fewer operations. There were 13, 16, and 10 neurosurgeons performing 5 or more procedures in those years.

It should be remembered that the number of procedures listed as psychosurgical is undoubtedly far greater than the number actually performed for the treatment of psychiatric disorders because of the many unspecified neurosurgical procedures designated psychosurgery for the reasons stated in this section (see table 1).

Nonrespondents

With regard to the 420 questionnaires not returned, there were a few letters from neurosurgeons of varying persuasions, giving their reasons for not responding—including more than one offering the advice that a prepaid, self-addressed envelope might produce a greater response. Some neurosurgeons who were opposed to psychosurgery wrote explaining their positions and giving names of neurosurgeons who were not members of their organizations and who performed psychosurgery. These were followed up.

Study of the names and affiliations of nonrespondents revealed that with two exceptions none had published clinical reports on psychosurgery or had received publicity in the numerous newspaper articles on psychosurgery making headlines at that time. Of

the two exceptions, one was known not to have been recently active in operating on psychiatric patients. The other was a surgeon whose work had been a focus of attention; the exact number of his cases was not known, but, on the basis of information from other sources, the number is more than compensated for in the above statistics.

With respect to the extent of psychosurgery by a number of nonrespondents, a series of inquiries was made of other physicians, principally psychiatrists practicing in the same geographical area. These inquiries, mainly in metropolitan areas of the United States, revealed that psychosurgery had been carried out by a few of the nonreporting neurosurgeons but in no case was there a significant amount. This included two neurosurgeons not listed in the membership of either the American Association of Neurological Surgeons or the Congress of Neurological Surgeons. It was concluded that the inclusion of all doubtful and unspecified operations under the category of psychosurgery (table 1) plus the statistical correction for nonrespondents more than allowed for procedures not reported.

DISCUSSION

Careful study was made of the published articles and statements of those neurosurgeons who had been the focus of charges of abuse of psychosurgery, while information was sought from other sources, mainly psychiatrists, who were likely to have some knowledge about patients who had been operated on by them. Information about the demographic aspects of patients was also sought from a sample of psychiatrists associated with published reports on psychosurgery. No information was developed which supported the accusations that were the impetus for the task force study.

The National Commission for the Protection of Human Subjects of Biomedical and Behav[illegible] issued its final report and recommend[illegible] March 1977. The APA Board of Truste[illegible] task force report in October 1976. The [illegible] tions and findings of the National Co[illegible] remarkably close to those of the task fo[illegible] difference between the recommendati[illegible] and those of the Commission was w[illegible] forming psychosurgery on minors. The [illegible] ommended that "with the present sta[illegible] psychosurgery should not be perfor[illegible] nors." The Commission, on the other h[illegible] wish categorically to deny children the p[illegible] tages of a new therapy that might be [illegible] effective than long-term use of other t[illegible] phasizing at the same time the neces[illegible] including court review.

Both studies concluded, among oth[illegible] psychosurgery may be an effective tre[illegible] resort in selected psychiatric disorders [illegible] desirable effects have been exaggerated [illegible] tion, often by erroneously attributing t[illegible] niques those adverse consequences w[illegible] the earlier prefrontal procedure. Both [illegible] cluded that there is no reliable evidence [illegible] surgery has been used for political p[illegible] control, or as an instrument for racist [illegible]

In the allotted space, it is not possi[illegible] analyses of the kinds and frequency of [illegible] surgical approaches now used or of the [illegible] conditions so treated. Neither has the in[illegible] garding the neurosurgical treatment of [illegible] been presented.

As mentioned earlier, there have bee[illegible] in the past to ascertain—but much gu[illegible] the number of psychosurgical procedu[illegible] in the United States. The high numbe[illegible] ents—78%—together with extensive in[illegible] ing the practices of those not returnin[illegible] naire should set at rest the fears th[illegible] aroused in the minds of so many.

Let it be hoped that the unfounded cl[illegible] those by psychiatrists, that thousands o[illegible] are performed annually for nefarious p[illegible] lated to the relief of otherwise intractal[illegible] disorders have ended and will no longe[illegible] anxieties of the public.

First-Rank Symptoms in the Postacute Schizophrenic: A Follow-Up Study

BY MARSHALL L. SILVERSTEIN, PH.D., AND MARTIN HARROW, PH.D.

Schneider's diagnostic system of first-rank symptoms (FRS) is acknowledged by psychiatrists throughout the world as a decisive basis for the diagnosis of schizophrenia. Recently, the authors' and others' works have challenged this view. This report examines the relationship between FRS, psychotic symptoms, prognosis, and outcome at the postacute stage. The assessment of FRS was made from an interview schedule (a modification of the Wing Present State Examination) developed for the systematic assessment of psychotic symptoms. The results question the utility of FRS as a primary diagnostic approach to schizophrenia, suggesting that Schneider's system may not be superior to other diagnostic approaches.

KURT SCHNEIDER'S diagnostic system of first-rank symptoms (1) is acknowledged by a large number of psychiatrists throughout many parts of the world as the decisive basis for a diagnosis of schizophrenia. Although widely used by psychiatrists throughout Europe, first-rank symptoms (FRS) as a diagnostic system are not as well known in the United States. Since important theoretical formulations and treatment strategies in schizophrenia require reliable diagnostic criteria, the investigation of the utility of a diagnostic system that is used as widely throughout the world merits careful study.

Despite Schneider's claim that, in the absence of an organic brain syndrome, FRS occur only in schizophrenic patients (1), recent reports by Carpenter and associates (2, 3) and Newmark and associates (4) have challenged the view that FRS are pathognomonic of schizophrenia. Our own research (5) has

described in *DSM-II*. Although Schneider did claim that in the individual case schizophrenia could be diagnosed in the absence of any FRS, his emphasis on their primacy in the diagnostic process has influenced recent applications of FRS as a complete system. Thus, our investigation also attempts to examine the relationship between FRS and psychotic symptoms, with a particular emphasis on the relative discriminating power of these indices in distinguishing important characteristics of relatively young schizophrenic and nonschizophrenic patients.

Our research examines the relationship between FRS, psychotic symptoms, prognosis, and outcome, using a larger sample than in our previous follow-up study. Specifically, the following questions are addressed: 1) How prevalent are FRS in schizophrenics and nonschizophrenics at the postacute stage? 2) Are FRS more sensitive than a broader range of psychotic symptoms in identifying schizophrenic patients at the postacute stage and in distinguishing between schizophrenics and nonschizophrenics? 3) Do patients with FRS differ from patients with a broader range of psychotic features in areas other than symptomatology? 4) Do major prognostic indices associated with premorbid history and the onset of illness predict whether FRS persist beyond the acute stage in a sample of young early schizophrenics?

METHOD

Patient Sample

The patient sample consisted of 126 patients hospitalized at Michael Reese Medical Center during relatively early phases of their disorder. These patients, who were between the ages of 17 and 35 years, were studied at the time of hospitalization and then later assessed during the posthospital period (an average of 2.7 years after discharge from acute psychiatric hospitalization). These patients were part of the ongoing multidisciplinary schizophrenia project being conducted at Michael Reese Hospital and the University of Chicago (8, 9).

The total sample consisted of 2 major subgroups: 72 schizophrenic and 54 nonschizophrenic patients. The schizophrenic population included a subsample of 10 acute schizophrenics, 18 paranoid schizophrenics, 6 schizo-affective schizophrenics, 27 relatively young chronic schizophrenics, and 11 patients in other subdiagnostic groups. The mean age of the schizophrenics was 22.7 years at the time of the index hospitalization. The nonschizophrenic sample was composed of 31 patients with depressive disorders, 16 patients with severe personality disorders, and 7 patients with other varied diagnoses. The mean age of the nonschizophrenic group was 22.1 years at the time of the index hospitalization. At the time of the follow-up assessment 47% of the schizophrenics were on phenothiazines. During the postacute period, the schizophrenics on phenothiazines had more psychotic features ($p<.01$) than those who were phenothiazine-free. In many cases, however, their poorer clinical condition may have been the reason for phenothiazine therapy. Thus, caution in interpreting the results comparing different medication groups is warranted, since the patients were not assigned to the medication groups on a random basis. The schizophrenics receiving psychotherapy at follow-up did not differ in the prevalence of FRS from those not receiving psychotherapy.

Data Collection on First-Rank Symptoms and Other Psychotic Symptoms

The subjects were contacted to appear for an interview that was part of a series of investigations studying psychosis and other major symptoms in schizophrenia (10, 11). The assessment of psychotic symptoms (including FRS) was obtained from a structured interview, the Psychotic Symptoms Inventory (PSI), which we developed using items from the ninth edition of the Present State Examination (12) and Strauss and Carpenter's modification of the eighth edition of the Present State Examination (13).

The interview covered 17 categories of psychotic symptoms, which were then combined into composite ratings on 3-point scales (1=symptom absent, 2=weak or infrequent features, or probable but not absolutely certain symptoms, and 3=symptom present). These composite ratings were in four areas: 1) delusions, 2) hallucinations, 3) other sensory aberrations and/or strange experiences, and 4) an overall psychotic symptoms summary rating. The Psychotic Symptoms Inventory (PSI) interview schedule and rating system was described in fuller detail in a previous report (5).

Each of Schneider's FRS was investigated systematically, and ratings (also on 3-point scales) were obtained for the individual FRS. In order to maximize precision in the assessment of these symptoms, careful and detailed inquiry was conducted with the special care required in defining FRS emphasized by Schneider and more recently by Wing and Nixon (14). A summary rating (based on the presence or absence of at least 1 FRS) was also obtained.

The specific interview questions for the assessment of FRS included those described by Carpenter and associates (2), who studied the following 8 FRS: audible thoughts, somatic passivity, thought insertion, thought withdrawal, thought broadcasting, made feelings, made impulses, and made volitions. We also obtained information on the following additional FRS identified by Schneider: voices arguing, voices commenting on one's actions, and delusional perceptions. Each of the 17 categories of psychotic symptoms included an item such as "What do you make of these experiences? Do they have a special meaning or significance for you?" Interviewers were trained to make careful distinctions between delusional perceptions and delusional notions; this is generally regarded as a particularly difficult discrimination. Thus, in order for a delusional perception to be judged present, positive responses were required to satisfy the following four criteria: 1) the

phenomenon is a *normal* perception (hallucinations and strange sensory experiences are excluded); 2) the perception is interpreted in a delusional manner with abnormal unrealistic significance ascribed to the perception (e.g., a salt shaker is perceived normally but is believed to be an omen); 3) special personal meaning or self-reference is present; and 4) special meaning or a quality of urgency is present.

Data Collection on Outcome and Prognostic Indicators

A second structured interview, administered as part of the follow-up evaluation, provided a systematic detailed assessment covering functioning in the areas of social and work adjustment and rehospitalization, as well as a global composite (15), during the 12-month period prior to the follow-up evaluation. Other ratings were systematically obtained at the time of index hospitalization, including the prognostic indicators used successfully by Vaillant (16, 17) and Stephens and Astrup (18) and the Phillips Scale of Premorbid Adjustment (19, 20).

RESULTS

Prevalence of First-Rank Symptoms

Using a larger sample than in our previous report (5), we determined that FRS occurred significantly more frequently among schizophrenic than nonschizophrenic patients during the postacute phase of their disorder ($\chi^2=8.05$, $p<.01$). However, only 24% of the schizophrenic patients showed definite evidence of Schneider's signs: thus, FRS occurred relatively infrequently among schizophrenics as a group. Of the 72 schizophrenics 76% were free of FRS at the postacute phase. The fact that only 4% of the 54 nonschizophrenics had FRS after the acute phase of their disorder could be considered as one type of evidence in support of diagnostic systems based on FRS.

These data are in accord with our previously reported findings that while FRS do not occur in most schizophrenics (diagnosed according to *DSM-II*) after the acute stage, they do occur more frequently in these patients than in nonschizophrenics. An important question centers around whether the schizophrenics with FRS differ from those with any psychotic symptoms when they are compared in areas other than symptomatology. This issue is explored later in this report.

Efficiency of First-Rank Symptoms Compared with a Broader Range of Psychotic Symptoms

In evaluating the utility of any diagnostic system for schizophrenia based on FRS, a question of central importance arises that has not been explored fully in the past. This question is whether the use of FRS as a key index for the diagnosis of schizophrenia is superior in any way to the use of other combinations of psychotic symptoms. Specifically, one value of a diagnostic system should center around its efficiency in identifying important characteristics of psychopathology associated with the syndrome. This raises the question of whether patients diagnosed schizophrenic on the basis of FRS show a different premorbid background, course, or outcome than the group of schizophrenic patients with any psychotic symptoms. Psychotic symptoms defined in other ways than FRS, for instance, are FRS associated with schizophrenic deterioration more consistently than other combinations of psychotic symptoms, or do they predict chronic schizophrenic outcome more accurately? The question is whether FRS are more useful as prognostic indices of schizophrenia than different combinations of psychotic symptoms. Unless Schneider's first-rank system can be demonstrated to be uniquely related to central characteristics of the syndrome (such as distinctive clinical course) in a uniform manner, it will be difficult to justify contentions that FRS have greater diagnostic validity than any other psychotic symptoms.

Major combinations of psychotic symptoms. The analysis of whether FRS identify an important subgroup of schizophrenics was suggested to us by our previous findings (5), which indicated that while many schizophrenics showed psychotic symptoms at follow-up, a moderate percentage of these patients did not. Therefore, analyses were conducted to examine combinations of psychotic symptoms to determine the relative efficiency of FRS compared with other psychotic symptoms in discriminating between schizophrenic and nonschizophrenic patients during the acute stage.

In order to examine some of these issues, we divided the schizophrenic sample into patients with and without psychotic symptoms, as assessed by the overall psychotic symptoms index and the various combinations of psychotic symptoms. The findings presented in Table 1 indicate that 1) in the group of schizophrenics with definite evidence of first-rank symptoms, 53% also displayed FRS, whereas the remainder 47% did not have any of Schneider's signs; 2) of the 28 schizophrenics with delusions of reference, 3) all of the 11 schizophrenic patients with auditory hallucinations also showed definite evidence of at least one FRS; and 4) 44% of the schizophrenics who reported strange experiences or sensory aberrations showed evidence of FRS.

Thus, of the *DSM-II*-diagnosed patients with psychotic symptoms during the postacute stage, 47% would not have satisfied criteria requiring the presence of FRS for a diagnosis of schizophrenia. This finding is similar to a recent report by Strauss and Gift (21), who observed that in a sample of first-admission patients less than half of those considered schizophrenic by *DSM-II* criteria also had FRS. Although there are substantial areas of overlap between these diagnostic systems, there nonetheless remain major areas of

ancy between Schneider's approach and other current approaches such as *DSM-II*—Carpenter and associates' "flexible system" (22), the New Haven Schizophrenia Index (23), Taylor and associates' criteria (24), and, to a lesser extent, Feighner and associates' criteria (25).

Comparisons among different psychotic symptom indices. An important question centers around the relative discriminating power of different psychotic symptom combinations in contrast to FRS. Specifically, we were interested in which combinations of psychotic symptoms at the posthospital phase yield the best discrimination between patients previously diagnosed schizophrenic and nonschizophrenic at the time of the index hospitalization.

Three major indices were thus compared: 1) FRS, 2) all delusions, and 3) a subset of delusions comprised of delusions of reference, control, and/or persecution. The differences between schizophrenics and nonschizophrenics were statistically significant on all three indices ($p<.01$, chi-square analysis). The index of all delusions identified 29 (40.3%) of the schizophrenics; 24 (33.3%) of the schizophrenic patients had delusions of reference, persecution, and/or control. The index of FRS identified fewer of the schizophrenics (N=17, 23.6%) than either of the two other psychotic symptom indices. Thus, for this purpose the FRS was the least effective of these three indices of psychotic symptoms at the posthospital phase. This result is of particular interest, since Carpenter and associates (26) reported FRS to be less effective than other combinations of signs and symptoms in identifying diagnosed schizophrenic patients at the time of index hospitalization. Very few of the nonschizophrenics (3.7%–7.4%) showed any psychotic symptoms (including FRS) when these three indices at the postacute stage were used.

It appears that although FRS after the acute stage had discriminating power in differentiating schizophrenics from nonschizophrenics, this approach did not offer the best differentiation between these patient groups. There appears to be no compelling evidence to suggest that FRS after the acute stage are better or worse than other indices of psychotic features in discriminating schizophrenic from nonschizophrenic patients when current standard *DSM-II* criteria are used for establishing the original diagnosis.

First-Rank Symptoms and Outcome

The data on several aspects of outcome functioning at the postacute stage indicated that both FRS and a broader range of psychotic symptoms were related to other aspects of functioning. In table 2, it can be seen that schizophrenic patients with FRS and those with definite evidence of any psychotic symptoms were functioning poorly in other areas, although these correlations were far from perfect.

These data on other aspects of functioning were used to examine whether FRS at follow-up were more closely related to schizophrenic outcome than other combinations of psychotic symptoms. The results for schizophrenic patients indicated that 1) 53% with FRS and 47% with a broader range of psychotic symptoms showed poor social functioning; 2) 59% with FRS and 53% with a wider range of psychotic symptoms had poor work or instrumental role functioning; and 3) 65% with FRS and 75% with any psychotic symptoms had been rehospitalized since the index hospitalization.

In each specific outcome area a comparable proportion of schizophrenic patients with poor outcome was regularly identified by both the index of overall psychotic symptoms and of FRS. In regard to these specific outcome assessments, it appears that the presence or absence of Schneider's FRS during the postacute phase was not an automatic correlate of outcome functioning. Although in select areas there was a limited, nonsignificant tendency for the schizophrenic patients with FRS to have a somewhat poorer outcome compared to those patients with any psychotic features at follow-up, the evidence was not compelling. Our data on relatively young schizophrenic patients do not suggest that FRS as the basis for a diagnostic system in schizophrenia offer unique advantages in characterizing outcome in schizophrenia as compared to other psychotic symptoms.

First-Rank Symptoms and Prognosis

We explored whether seven major prognostic indices obtained at the time of the index hospitalization predict FRS during the posthospital period. These seven prognostic indices included 1) the Phillips Scale of Premorbid Social-Sexual Adjustment (19, 20), 2) acute onset, 3) precipitating factors, 4) emotional blunting on admission, 5) premorbid social adjustment, 6) premorbid work adjustment, and 7) premorbid schizoid personality (16–18). A series of correlations was obtained between each of these prognostic variables and both FRS and the overall psychotic symptoms index.

The results indicated that FRS at the postacute stage were not predicted by any of these prognostic variables. All of these correlations were very low and statistically nonsignificant. The absence of a relationship was also observed between these prognostic variables and the overall index of psychotic symptoms. Therefore, these data indicated that major prognostic indices used by Vaillant, Stephens, and others did not appear to be predictive of the occurrence of FRS after the acute stage, nor, for that matter, was there a strong relationship between these prognostic indicators and any type of psychotic symptomatology at the postacute stage.

DISCUSSION

After combining the results from several substantive areas of investigation, we question whether FRS are more important than any other psychotic features in schizophrenia.

With regard to prevalence, our data indicate that Schneider's FRS occur more frequently in schizophrenic than in nonschizophrenic patients at the postacute stage. This suggests that these symptoms are likely to persist over time for select patients and thus show a moderate degree of continuity over the long-term course of the disorder. The fact that some of our preliminary indications suggest that FRS may tend to be more prevalent among chronic and paranoid schizophrenic patients could offer some limited evidence supporting the utility of FRS, providing that this trend continues to hold up. However, FRS were not very common in the present sample of young adult schizophrenics, and, in addition, when psychotic symptoms of any type were present at the postacute stage, these psychotic features frequently were not FRS.

The comparison of the relative discriminating power of FRS and other psychotic symptoms indicated that FRS after the acute phase offer no more powerful distinctions between patients diagnosed schizophrenic and nonschizophrenic at the time of the index hospitalization than a variety of other combinations of psychotic symptoms. Therefore, there does not seem to be an apparent advantage in Schneider's system compared with other systems based on alternate combinations of psychotic symptoms in discriminating schizophrenic from nonschizophrenic patients at the postacute stage. Hyperkinetic/Aggressive Boys in Treatment: Predictors of Clinical Response to Methylphenidate

BY JAN LONEY, PH.D., ROBERT J. PRINZ, ED.S., JOEL MISHALOW, M.A., AND JESSE JOAD

Data on 84 nonretarded boys aged 6–12 with the hyperkinetic/MBD syndrome were drawn from a comprehensive, longitudinal investigation in the interest of identifying factors that contribute significantly to variation in clinically rated improvement during treatment with methylphenidate. The size of the multiple correlation (R=.50) indicates that 25% of the variation in the children's response to methylphenidate is jointly predictable from age at referral, degree of perinatal complications, and score on the hyperactivity factor. The authors discuss stepwise multiple regression analysis as the method of choice in drug response prediction studies and the possible effects on the results of such studies of differing definitions of improvement.

EXPERIENCE, CLINICAL LORE, and reports of controlled studies have led many physicians to prescribe CNS stimulant medication as the initial and primary treatment for the child diagnosed as having hyperkinetic reaction or minimal brain dysfunction (HK/MBD). There is little doubt that stimulant medication has at least a short-term positive effect on the behavior of a certain percentage of hyperactive children. At times the behavioral effect is dramatic, with a marked reduction in activity level and fidgetiness, a lengthened attention span, etc. However, HK/MBD children do not form a homogeneous group, and it is well documented that stimulant medications are not equally effective in the management of all cases. Recently cited examples of the overuse and misuse of these drugs (1) and studies describing their potentially dangerous side effects (2) remind us that scrupulous attention must be focused on the question of who is to receive such medications.

Predicting the response of hyperkinetic children to stimulant medication has been a small but significant issue in the literature (3–5). It is apparent that this body of research is in considerable disarray, with some predictive factors operating inconsistently at different times in opposite directions from one study to another. This is probably due at least in part to the use of various definitions used to select treatment samples; heterogeneity of drugs, dosages, and lengths of treatment time employed; variations in design and control procedures; and differing criteria considered to measure improvement (3).

Although certain possible predictors are often advanced (e.g., "organicity" or attention deficits), there are few cross-validation data. Furthermore, the relationships found between predictor and outcome variables, even when statistically significant, rarely are more than "modest" in size. Thus, as Sprague (6) noted, "to date no basis exists for predicting whether a specific hyperactive child will benefit from drug intervention, or for determining which medication will be most effective and what the minimum effective dosage is for him."

The present study was stimulated by an interest in identifying factors that contribute significantly to variation in clinically rated improvement among HK/MBD boys during a treatment trial of methylphenidate.

METHOD

The Iowa HABIT project (Hyperkinetic Aggressive Boys in Treatment) is a comprehensive, longitudinal investigation of the hyperkinetic/minimal brain dysfunction syndrome. The data to be considered here were drawn from a part of the project that focuses on information contained in outpatient medical charts routinely maintained by the University of Iowa Psychiatry Service.

Subjects

Of all 4- to 12-year-old boys seen for outpatient diagnostic evaluation by the University of Iowa Child Psychiatry Service between January 1, 1967, and September 1, 1972, 482 had not been treated with drugs within the previous 6 months. Sixty-two percent (300) were recommended by senior psychiatrists for trials of cerebral stimulants because their history and symptom picture suggested minimal brain dysfunction. Of these 300 boys, 59 were excluded from the HABIT project sample because either their tested IQ's were less than 70 or they were suffering from peripheral

0002-953X/78/0012-1487$0.50 © 1978 American Psychiatric Association

sory loss, major psychosis, epilepsy, cerebral palsy, or unequivocal brain damage.

The HABIT sample was further limited to boys whose drug treatment had been initiated and followed by staff psychiatrists and/or psychiatric residents of the University of Iowa Child Psychiatry Service. Subjects were included only if drug treatment had started within 6 weeks of the day of the outpatient evaluation and at least one treatment progress note had been placed in the medical record before termination of drug treatment, addition of other drugs or therapies, or referral to a local physician for drug follow-up.

Application of these exclusionary criteria resulted in a sample of 135 boys. This HABIT group includes boys from both rural and more urban areas of Iowa and several surrounding states, and 98% of the sample is white, a figure similar to that for the Iowa general population. The families' Hollingshead and Redlich (8) socioeconomic classes were as follows: I and II, 21%; III, 33%; IV, 26%; and V, 20%. Of the 135 boys 95 (70%) were given an initial diagnosis of hyperkinetic reaction of childhood (*DSM-II*, 308.0).

Before we performed the analyses that will be described, a more homogeneous subsample with minimal amounts of missing data was formed by selecting boys who were 1) between 6 and 12 years of age at the time of the outpatient evaluation, 2) living in intact families (i.e., both a mother and father figure present in the home) at the time of referral, 3) placed on methylphenidate within 6 weeks of the outpatient evaluation, and 4) between 12 and 18 years of age at the time of subsequent 5-year follow-up (9). The resulting subsample consisted of 84 boys whose average age at referral was 9.2 years. The mean full scale IQ of the 61 who were given the Weschsler Intelligence Scale for Children at referral was 101.08 (SD=15.18, range=72–139).

Diagnostic and Treatment Procedures

The initial outpatient diagnostic evaluations were scheduled one per morning and supervised by whichever of two senior psychiatrists was assigned to the day in question. The supervising psychiatrist presided over an afternoon meeting at which the psychiatric resident and the outpatient staff members (social worker, psychologist, and educational consultant), who had assessed the child and his family that morning, presented verbal accounts of the psychiatric interview and physical-neurologic findings, social-developmental history, psychological and educational test results, the school report, etc.

The senior psychiatrist was responsible for making the psychiatric diagnosis, prescribing a course of treatment, and dictating a lengthy staff summary. The resident and each of the outpatient staff members dictated a detailed narrative report of their interactions with and impressions of the child and/or parents; these were also typed and placed in the child's chart as the medical-psychiatric summary, the social summary, the psychological report, and the educational report.

After the staff evaluation, most cases were assigned to the psychiatric resident for drug regulation and follow-up. Medication levels were determined clinically. The maximum daily dosage of methylphenidate during the treatment period ranged from 5 to 85 mg (mean=37.5).

Predictor Variables

Symptom severity at referral. Among the variables that have been assessed (9) are ratings of each child by two judges on the severity of primary (central) and secondary (resultant) HK/MBD symptoms (10–12). A pair of advanced graduate students in school psychology independently reviewed the staff, medical, and social summaries and psychological and educational test reports for each child and then rated on a 5- or 6-point scale the severity and/or frequency of 6 primary symptoms (hyperactivity, fidgetiness, inattention, judgment deficits, negative affect, and uncoordination) and 4 secondary symptoms (aggressive interpersonal behavior, compulsivity, self-esteem deficits, and control deficits). The effective rater reliabilities (13) for the symptom ratings ranged from .73 to .92. For analysis, the two judges' ratings were averaged to produce a composite severity score for each child on each symptom.

In another study, Loney and associates (14) performed a principal axis factor analysis and identified two relatively independent factors in these judges' chart ratings of primary and secondary symptoms at referral. The first factor, which accounted for 44.6% of the factor variance, consisted of negative affect (e.g., excitability, irritability, low frustration tolerance), aggressive interpersonal behavior (e.g., bullying, fighting, refusing to mind), and control deficits (e.g., delinquent acts, evasion of rules). The second factor, which accounted for 23.4% of the factor variance, consisted of hyperactivity (e.g., always on the go, overactivity, restlessness), inattention (e.g., inability to concentrate, distractibility, forgetfulness), and judgment deficits (e.g., immaturity, impulsivity). These two factors, labeled aggression and hyperactivity, respectively, are used in the present investigation as the two measures of symptom severity at referral.

Parenting styles. Among the family variables that have been assessed (9) are ratings of each parent by two independent judges on 9 parenting variables. The same set of chart summaries and reports was used to make both the parent ratings and the symptom severity ratings, but the judges in each instance were a different pair of advanced graduate students. The parent rating variables included separate 7-point ratings along both the love-to-hostility and autonomy-to-control parenting style dimensions (15). The effective rater reliabilities (13) for the parenting ratings ranged from .51 to .83. Again, for each dimension the two ratings for each parent were averaged to produce a composite score.

Neurologic and perinatal status. The child's age and a synopsis of the psychiatric resident's neurologic and

physical findings as detailed in the medical summary were retyped. The content of these synopses varied, but they included such presumably salient material as observations of fine and gross motor movement and tests of synkinesia, graphesthesia, tandem walking, cranial nerves, alternating motion rate, postural reflexes, etc. (16). Based on these synopses, two faculty members (a pediatric neurologist and a pediatrician/child psychiatrist) independently rated soft signs of neurologic impairment on a 5-point scale.

Similar independent ratings were made by the pediatrician/child psychiatrist and an obstetrician/child psychiatry resident based on a separate synopsis of the narrative summary of perinatal events as reported by the mother (e.g., mother's reproductive history, details of pregnancy and delivery, child's condition at birth).

The effective rater reliabilities (13) for these two sets of synopses were .83 and .89, respectively, and composite ratings were again used for each.

Socioeconomic status. In devising a measure of socioeconomic status (SES), a preliminary factor analysis was used to reduce by empirical means a relatively large set of conceptually similar variables to a smaller group of more or less independent dimensions that would account for most of the variance in the data set. The variables that loaded on the single resultant SES factor and that were therefore used to generate an SES factor score for each child were father's education (8, 17), mother's education, father's occupation (8, 17), family income, and psychiatric fee. Three categories constituted the psychiatric fee variable: private or full fee, clinic or partial fee, and state (i.e., indigent) or no fee.

Selection of predictors. Based on considerations of completeness, reliability, saliency, scope, and parsimony (18), the final list of 11 variables selected as potential predictors of drug response was age at onset of referral problem, age at referral, perinatal complications rating, neurologic signs rating, aggression and hyperactivity factors, SES factor, and ratings of the mothers and fathers on the love-to-hostility and autonomy-to-control parenting dimensions.

Criterion Variable

All of the children's study charts contained at least one medication progress note. Many of these were written summaries by a physician or social worker of a verbal account of positive, negative, or no change obtained from a parent, teacher, or local professional person. Many other progress notes were written summaries of behavioral observations of and interviews with the child during a return visit to the clinic. Other progress notes took the form of letters from the child's parents or teachers reporting on his condition, letters from a staff person to the child's school or local physician, repeated educational and/or psychological test reports, etc.

The project secretary removed from each progress note any reference to the patient's name, age, or grade in school; the names of all staff persons involved in the case; and any information indicative of socioeconomic class, parent-child relationship, or other variables hypothesized to be related to improvement. The entire set of over 800 amended progress notes was then retyped, 1 per page, and placed in random order. Each note was independently rated on a 5-point response to medication scale (19) by two experienced psychiatricians. The progress notes were then replaced in temporal sequence for each child, and an overall improvement rating was independently assigned to each case by the two raters. Progress notes from an average of 6.8 months of treatment with methylphenidate were rated for each child. Effective rater reliabilities for these drug response measures ranged from .8[illegible] to 9[illegible] and composite ratings of each measure were derived for each child.

A factor analysis was used to reduce empirically the set of several measures of medication response, each of treatment, dosage, and side effects. Six response measures loaded on the single resulting factor and were therefore used to generate for each child a response to medication factor score that served as the criterion variable. These 6 measures were the first response to medication, the first response to the highest dose, the highest rated response, the last response to medication, the mean response over the first 3 months, and the overall response.

RESULTS AND DISCUSSION

Three of the 11 predictors correlated significantly with the response to medication factor score: age at referral ($r=.36$, $p<.001$), perinatal complications ($r=.25$, $p<.05$), and the hyperactivity factor ($r=[illegible]$, $p<.10$). The stepwise multiple regression analysis to predict drug response took these 3 predictors, in order, to produce a multiple correlation of .50, indicating that 25% of the variation in children's response to methylphenidate is jointly predictable from age at referral, degree of perinatal complications reported by mothers, and scores on the hyperactivity factor.

The fact that age is an important predictive variable is puzzling. The child who is referred at an older age apparently differs from the younger child in a way that affects his response to methylphenidate. The appearance of the hyperactivity factor as an additional independent predictor in the analysis indicates that the way in which the older child differs is not simply that he is more hyperactive. There is some evidence that important aspects of HK/MBD children's problem behavior tend to diminish naturally with age (20), thus raising the possibility that the association found here between age and improvement is artifactual.

Some previous investigators (21, 22) have reported a relationship between drug response and one or more variables from a subset of "organic" predictors. The support lent to the hypothesized connection between organicity and drug response by the appearance of

perinatal complications in the present prediction equation must be balanced against the nonappearance of the more direct assessment of neurologic signs.

The least important of the 3 significant predictors of drug response in the present study is the hyperactivity factor, an unweighted sum of the child's standard scores on the symptom ratings of hyperactivity, inattention, and judgment deficits (impulsivity). Its appearance as a predictor is compatible with a connection between inattention and drug response recently hypothesized by Barkley (3).

Although a well-known study by Conrad and Insel (21) linked parent characteristics and drug response, we found no parenting or SES predictors of response to methylphenidate. Further, the child's degree of aggression did not influence drug response. This study thus does not provide a basis to advocate withholding drug treatment in the belief that environmental and symptomatic complications preclude good response. On the other hand, the fact that older children in this study responded better to medication than younger ones means that those practitioners who would opt for the use of CNS stimulants as a "last resort" should find nothing in these data to dissuade them.

Few investigators seeking to identify possible predictors of HK/MBD children's responses to stimulant drugs have used the stepwise multiple regression method, although it has several appealing features that probably make it the method of choice. Like ordinary two-variable linear correlation (Pearson r), this technique enables one to identify independent variables that are correlated with (i.e., that predict or contribute to variation in) the dependent variable. Unlike ordinary correlation, however, stepwise multiple regression enables one to assess the relative importance of each of the independent variables in terms of the specific amount of variance in the criterion variable for which it independently accounts. In the present analysis, for example, one can conclude not only that scores on the hyperactivity factor predict scores on the response to medication factor but also that 1) the hyperactivity factor is a relatively less important predictor than age at referral or perinatal complications, and 2) it makes a predictive contribution independent of both age at referral and the perinatal complications ratings. Because the addition of the hyperactivity factor increases the multiple correlation from .44 to .50, it is also possible to conclude that the hyperactivity factor accounts independently for only .36% of the variation in scores on the response to medication factor. Since response to stimulant drugs is probably multiply determined, the continued use of stepwise multiple regression or other multivariate methods (23, 24) holds considerable promise.

Although correlational data do not allow the identification of cause and effect, the three independent variables in this study (perinatal complications, age at referral, and severity of hyperactivity) could plausibly be considered actual precursors of drug response. One could in fact use a multiple regression equation to predict in advance of prescribing medication a precise rating for a given child on a medication response scale, and one could base the decision to initiate or to withhold medication on the value of that predicted rating. Of course, careful derivation and cross-validation of any such predictive equation would be necessary. Those who believe that there are no significant risks in using medication might argue that such a predictive approach is not even needed; all that is required is to initiate a drug trial and to observe response. Given the modest size of the multiple correlation in the current study and the likelihood of its shrinkage on cross-validation, the clinical utility of these three identified predictors is probably limited. An identical point could be made concerning other predictor variables proposed to date (21, 22); their present interest is more theoretical than practical.

The current study used a global response to medication score derived retrospectively from contemporary narrative progress notes. This approach has disadvantages that operate to reduce the reliability and, consequently, to compromise the validity of the findings. The data are less objective, focused, and systematic than one would wish, and they are filtered through the multiple perspectives of parents, teachers, treating physicians, and raters. For these reasons, one might consider the present results as generating hypotheses about predictors of response to methylphenidate rather than as identifying predictors. However, these data are derived from exactly the sort of global response information that clinicians routinely collect and use in assessing effects and titrating dosages of medication. To this extent, the findings here should reflect predictions that could actually be made in similar settings.

Much of the difficulty in arriving at a settled opinion on the predictors of response to CNS drug treatment arises from difficulties in defining response. Some investigators, for example, have used an initial response or improvement measure, while others have employed a longer-term response or outcome measure. Initial response or improvement tends to be framed in self-relative terms ("He is more attentive than he used to be") or derived from change scores. Long-term response or outcome tends to be expressed in terms of severity ("He is quite attentive") or in terms of the hypothetical normal child ("He is more attentive than most"). It is one thing if an improved child is one who merely has less of a problem than he used to have and quite another if he is one who has less of a problem than others do. As the work of Weiss and colleagues (25) has recently suggested, the connection between early response to treatment and condition at follow-up is far from simple or strong. In addition, improvement measures based on symptom severity may yield different results from improvement measures based on behavioral frequency.

There appears to be a tendency for the more severely hyperactive child to be rated as having a better response to medication. This might mean 1) that the

more severely hyperactive child actually responds better to medication, 2) that what improvement he does show is merely more discernibly different from his previous high rate of hyperactive behavior than is an equal improvement in a child who was less severely hyperactive or more variable before treatment, or 3) that high hyperactivity scores are simply more likely to display a statistically artifactual regression to the mean which would be mistaken for improvement. Few studies to date have attempted to disentangle these possibilities.

The Group Psychotherapy Dropout Phenomenon Revisited

BY LESLIE M. LOTHSTEIN, PH.D.

In this two-year study, patients referred for group therapy were extensively screened and carefully prepared for the therapy. In spite of this effort there was a 29% dropout rate after group therapy began. All of the therapists reported that they disliked the patients who dropped out, and many of these patients were seen as hostile toward the therapists. The author suggests that for many groups the dropout phenomenon may be basic to the establishment of group cohesiveness and that instead of trying to prevent or reduce the dropout phenomenon, efforts should be directed toward reconceptualizing the more positive aspects of it.

THE DROPOUT phenomenon, which is reported to occur during the early phases of group therapy, has been recognized as an important obstacle to group formation (1-3). In a classic study of group therapy dropouts, Yalom (4) reported a 36% overall dropout rate during the initial phase of group therapy. He attributed the dropouts to nine factors, one of which, the patient's lack of orientation to group therapy, played a key role. Regardless of the therapeutic approach to group therapy, the dropout rate seems to average about 30%, with a range of 25% to 50% (5, 6). A patient's premature termination of group therapy can pose a significant problem for group formation; Yalom (4) has suggested that adequate patient preparation for group therapy be employed to prevent or reduce this phenomenon.

Although preparing patients (and therapists) for group therapy is well recognized as an important factor in preventing or reducing early dropouts, it is a difficult task even for the experienced therapist (7-9 and Lothstein[1]). The techniques of pregroup patient preparation (PGPP) vary considerably and include having patients listen to tapes of group therapy sessions (10), providing written literature about groups (11), and conducting pregroup individual sessions (8) and pretherapy group sessions (12). What these PGPP techniques have in common is the underlying philosophy that dropouts should be discouraged and that one can prevent or reduce the dropout phenomenon by introducing clarity, structure, goals, and certainty and by reducing ambiguity in the early phases of group therapy.

While group therapy researchers have looked for ways to prevent or reduce the dropout phenomenon, no one has seriously considered some of the positive aspects of this phenomenon. It is my aim in this paper to show that the dropout phenomenon has not been fully understood and that future research to prevent or reduce dropouts should be reconsidered. The findings suggest that the dropout phenomenon may serve a positive clinical function for increasing the integrity of the group while consolidating group cohesiveness.

When I first began my investigation of the dropout phenomenon, I hoped to empirically demonstrate that a structured group therapy training program could prevent or reduce early dropouts by employing a combination of intensive trainee supervision and course work around the problems raised in the initial phases of forming a group. Because of the large effort to prevent or reduce dropouts, it was surprising to learn that approximately 30% of the patients still dropped out of the groups. The findings presented here should be of interest to group therapists who have taken the inevitable 30% dropout rate too personally.

THE STUDY

The results reported here stem from a two-year study of group therapy dropouts at Case Western Reserve. The patient population was drawn from Cleveland's diverse urban community and was a heterogeneous group with respect to social, economic, ethnic, racial, and educational backgrounds. The study was designed to determine whether the dropout phenomenon could be controlled through a combination of factors introduced into the training program. Advanced trainees with diverse educational, vocational, and theoretical backgrounds were enrolled in the program. The student therapists reflected a spectrum of trainees found in most training centers and included three psychiatric residents, nine psychology interns, two social workers, and two staff psychologists. The theoretical orientation of the group reflected a combination of approaches, but the primary focus was on expressive-dynamic group psychotherapy.

Dr. Lothstein is Assistant Professor of Psychology, Department of Psychiatry, University Hospitals of Cleveland, 2040 Abington Rd., Cleveland, Ohio 44106.

The author wishes to thank Mary Anne Lothstein, M.Ed., Alan Feirstein, Ph.D., David Logan, M.D., David Agle, M.D., and two unnamed reviewers who provided thoughtful criticism and constructive help in preparing this manuscript in its final form.

All of the trainees were required to participate in a 2½-month seminar that focused intensively on the PGPP interview. A standardized PGPP interview was introduced.[2] Guidelines for PGPP interviewing were established, and the trainees observed the director of the training program interview prospective group patients using the PGPP method. In addition, all trainees were provided a minimum of 1 year of supervised group therapy experience (using cotherapy teams) and an option to participate in a continuing awareness group for group therapists.

Pregroup Patient Preparation Interview

In the PGPP the patient is systematically oriented to group therapy by means of a standardized interview technique in which three main areas of inquiry are pursued: educative, sensitizing, and evaluative. These areas describe predetermined functions, rules, and procedures that the therapist subscribes to during the PGPP interview. Within each of the three areas of inquiry there is an inventory of questions to be asked of the patient (a total of 27 questions). Although each of the three areas of the PGPP interview may be logically distinguishable from the others, in reality they are intermixed and during an interview may be indistinguishable.

In the educative part of the interview the group therapy contract is spelled out, and the patient is provided with important information about the pragmatics of the group therapy offered. These procedures provide the patient with a reality base with which to assess his or her therapeutic expectations and demystify group therapy.

In the sensitizing part of the interview the therapist helps the patient to confront and work through his or her expectations, fears, concerns, anxieties, hopes, and ambivalence about entering group therapy. In addition, the patient's interpersonal skills and styles are explored along with his or her ability to empathize, be supportive, give and take, be assertive, and benefit from group therapy.

In the evaluative part of the PGPP interview the therapist identifies the patient's level of psychopathology, isolates the patient's primary defensive strategies, and assesses his or her strengths and weaknesses vis-à-vis the other group members. Although a formal diagnosis is helpful, it is also important that the therapist assess the patient's interpersonal functioning and try to determine the effect he or she will have on other members of the group.

The value of employing a standardized PGPP interview technique is that since all patients are similarly prepared for group therapy, it is easy to research the effects of patient preparation on other group measures.

[2]Lothstein LM: Preparing patients for group psychotherapy; two models for the pregroup psychotherapy evaluation; techniques and interview problems in preparing patients for group psychotherapy (unpublished papers, 1975).

Procedure and Findings

Ninety patients initially assigned for g[illegible] were interviewed by the director of the g[illegible] training program and were then assigned [illegible] therapy groups for further evaluation an[illegible] for group therapy. During this period [illegible] were intensively supervised around th[illegible] the initial phase of group therapy and rec[illegible] training on the problems raised durin[illegible]

Of the 90 patients assigned to group [illegible] eventually entered group treatment (an [illegible] rate of 47%). Of these 47 patients, 31 wer[illegible] 16 were men (a ratio of approximately [illegible] tion, there was almost a 4:1 white to bla[illegible] tio, with 37 white patients and 10 black[illegible] white patients consisted of an almost equ[illegible] men and women, while all of the black [illegible] women. The average age was 22.7 years [illegible] women and 24.1 years for men).

About 11 patients were referred to e[illegible] groups. About 2 patients per group dropp[illegible] entering therapy (during their PGPP inte[illegible] another 2 per group eventually dropped [illegible] tering group therapy (all but 1 of the drop[illegible] before the 12th session). It was found tha[illegible] stabilize the patient groups at an average o[illegible] per group, a patient pool of twice that size [illegible]

In addition to the 47% dropout rate fr[illegible] group therapy referrals, there was a 29% [illegible] (N=13) once therapy began. None of [illegible] contributed significantly to a large part [illegible] However, over 70% of the patients (N=34, [illegible] group treatment remained in it. This figu[illegible] than Koegler and Brill's figure of 58% for [illegible] ric outpatients who completed their treatm[illegible] it is consistent with figures from other gr[illegible] research.

The initial pregroup dropout rate may ha[illegible] lated to initial selection criteria that we[illegible] ciently stringent, but it is within the expec[illegible] for group therapy. In the present sample, [illegible] to have a particularly difficult time stay[illegible] therapy. All of the black male patients [illegible] during the initial evaluation phase. In add[illegible] male patients (N=8) accounted for 65% o[illegible] dropped out after entering group therapy. [illegible] ings will be discussed below.

All of the patients who dropped out e[illegible] entering the group or during the course o[illegible] were interviewed by the director of the p[illegible] ther on the phone or in person (100% res[illegible] each patient was asked to complete an [illegible] questionnaire focusing on his or her react[illegible] group therapy experience (40% response. [illegible] addition, all of the patients who completed g[illegible] apy filled out the same questionnaire, and a[illegible] the therapists were interviewed about the re[illegible] patients either not entering group therapy or [illegible] out of a continuing group.

The questionnaire included 18 direct questions (to be completed by the patient) relating to one's overall group therapy experience. The pregroup dropouts who were interviewed on the phone were asked those questions which related to pregroup patient preparation. The patients who dropped out before entering group therapy (i.e., during the evaluation interview) fell into two categories: those who requested individual therapy (20%, N=8) and those who decided not to pursue treatment (27%, N=11). All of the patients who dropped out after entering group therapy reported that they had been adequately prepared for the group, and none of them requested additional treatment. Based on the patients' questionnaire responses, there were no overt characteristics that distinguished the dropouts from the patients who remained in group therapy. However, based on the therapists' reports, there were definite differences between these two groups. These findings will be elaborated below.

Of all the patients surveyed who remained in group therapy, only 1 felt that she was not adequately prepared for the group. All of the others felt that they had received more than adequate pregroup preparation, and all of them reported that they felt positive about their group experience and would recommend group therapy to other patients.

DISCUSSION

In spite of a strong emphasis on pregroup patient preparation, there was a 29% dropout rate for the patients who entered group therapy. Efforts to reduce or prevent group dropouts were initially deemed a failure. The dropout rate seemed high given the fact that the outpatient clinic initially referred suitably motivated patients to the program, the program director evaluated the patients' motivation and suitability, and the cotherapists further evaluated and then prepared the patients for group therapy. At first I wondered whether the extensive screening process might have accounted for the dropouts, especially the male dropouts. However, the overall stability of the therapy groups compared with those several years earlier ruled this out. The group stability was attributed primarily to the effectiveness of the PGPP program. In this sense, preparing a patient for group therapy had an important effect on controlling the early dropout phenomenon, which may lead to group dissolution.

Six of the 8 groups had a male and a female cotherapist, and 2 of the groups had same-sex cotherapist teams (1 male and 1 female team). The type of therapy team did not affect the dropout rate.

All therapists received extensive supervision on the PGPP interviewing, and only those patients deemed suitable for group therapy were assigned. In this way initial questions of suitability for group therapy, degree of psychopathology, and interpersonal styles and abilities had already been assessed by senior clinicians, and some idea of a patient's likelihood to benefit from group therapy was assessed. In addition, all of the patients expressed a positive interest in obtaining group therapy during their initial outpatient evaluation. Thus some of the more formidable work had already been carried out even before the cotherapists interviewed the patient.

The overall composition of the patients who dropped out before the first session differed from that of the group entering therapy in only one aspect: all of the black men in the sample (N=6) dropped out before entering therapy. One factor that may have accounted for so many black men dropping out was the lack of any black therapists. It is also theoretically and practically possible that the therapists and group members were racially biased and transmitted their values to these patients. However, the fact that black women remained in the group seems to preclude racial bias as a sole explanation for the dropout rate among black men. Although the therapists may have perceived the black men as more threatening and dangerous, none of them were dangerously impulsive individuals. It was puzzling that none of the black men requested alternative treatment and that they were unanimous in the view that racial factors were not involved in their reasons for dropping out of group therapy. The phenomenon has not yet been adequately explained.

The fact that white men accounted for 65% of the dropouts (N=8) once group therapy began was also an intriguing finding. It is not known if this phenomenon is peculiar to our clinic or whether men are more stressed by the early issues of group therapy and need to be addressed in a special way.

In reviewing the therapists' explanations for why a patient dropped out of group therapy, the ideas of stress and fit occurred regularly. Therapists saw the initial period as quite stressful for some patients, who either became scapegoated by the group or withdrew because of a fear of involvement. Although the patients' reasons for dropping out focused on such factors as no longer needing treatment and scheduling problems, the therapists focused on dynamic reasons for the dropouts. All of the therapists reported that they disliked the patients who dropped out, and many of those patients were seen as hostile toward the therapist. This finding suggested that there were some very clear characteristics that differentiated the dropouts from the patients who remained in therapy.

It is well known that during the initial period of therapy, it is sometimes difficult to arouse patients' hostile feelings toward the therapist. For some groups it appeared that the group's therapist-directed aggression was being displaced onto the potential dropout, often in the form of not listening to the patient, being unsupportive, interrupting the patient, or being generally unconcerned about the material the patient brought up. In some cases it appeared that the therapists may have been supporting displaced aggression in order to enhance their attractiveness as leaders. By confronting a patient's resistance and expelling him, the leader may have been attempting to consolidate control over the

group by having other group members fearful of the therapist. Some leaders may unconsciously engage in this ritual and may be acting out the group's hostility toward the patient, that is, doing the group's work while also acting out their own sadism. In a dependency group in which there is a patient need for a strong leader, the group members may actively support such a strategy.

Some of the patients who dropped out were able to express their disappointment that the therapists and other patients were disinterested and unsympathetic with them. When these issues were brought back to the group members, the patients' disinclination to discuss the matter supported the dropouts' views. Furthermore, most of the remaining patients stated that the dropouts really did not fit into *their* group.

In no group did the issue of a patient's dropping out arouse the feeling among patients of being on a sinking ship. Rather, the effects of the group's choice not to accept one or two patients seemed to consolidate a feeling of belonging and a sense of "we-ness" among group members that resulted in good group attendance and which, as Yalom (3) pointed out, is a "precondition of effective therapy." Because our training program focused on some of the more thorny issues of group solidarity, we did not experience the phenomenon of the high patient-therapist turnover that usually leads to a noncohesive group.

In analyzing the results of the early group therapy dropouts, it was considered how the diversity of the therapists' backgrounds and level of training, the use of cotherapists, and the inadequate handling of immediate countertransferance issues may have contributed to the 29% dropout rate. In addition to these factors, it was considered how the patients may have been inadequately assessed or misdiagnosed or how some of the 9 factors related to group therapy dropouts reported by Yalom (4) may have been operating against us.

Whatever explanations arrived at to account for the dropout phenomenon, one thing was clear: after the 12th session the group membership stabilized and the dropout phenomenon was no longer in evidence. At that point the most outstanding feature was the cohesiveness of the groups.

During the initial 12 sessions considerable stress was placed on the patients to deal with such issues as belonging, acceptance, and inclusion. Every group went through an initial period of turmoil in which the hostility among group members and the therapists led to the expulsion or sacrifice of a few group members. This process of expulsion or sacrifice helped each [redacted] become a more cohesive unit in which a sense [redacted]ess or "we-ness" was acknowledged. The [redacted]for group cohesiveness helped each group [redacted]ndaries and identity as a group. As each [redacted]ned its potential membership and decided [redacted] be included, the group established its spe[redacted]s a separate, independent entity that was not [redacted]and dependent. Once a sense of integrity was [redacted]ed by the members who had some control over group membership, the boundaries [redacted] were firmly established and therapy could [redacted]

Although some groups may develop a [redacted] cohesiveness without the need to sacrifice [redacted] is suggested that for many groups the [redacted] may be basic to the establishment of [redacted] ness. Indeed, patients previously labeled [redacted] may actually serve an important function [redacted] expression of group hostility.

Instead of trying to systematically prev[redacted] the dropout phenomenon, we ought to be [redacted] ceptualize the more positive aspects of it [redacted] pist who confronts a patient's initial res[redacted] tending the early meetings may, in addition [redacted] his or her role as therapist, in some case[redacted] pating in a ritual of group expulsion and [redacted] acting out an important group function [redacted] therapist's reported fear of the group's d[redacted] ing the early dropout period may, in fact [redacted] flect the therapist's anxiety and guilt o[redacted] hostility toward the so-called dropout p[redacted]

These findings suggest that the 30% [redacted] student therapist-led group therapy m[redacted] ly preventable. Families and Hospitals: Collusion or Cooperation?

BY HENRY T. HARBIN, M.D.

The author describes the therapeutic problems that can arise on a family-oriented psychiatric inpatient service. The stress emerging from the therapeutic demands on and changes in the internal structure of the family may cause the family to seek to reestablish its internal equilibrium by changing the hospital staff and structure at the ward level, department level, and the hospital administration level. These transactions between the hospital and families, which are complex, are extremely important to recognize because they can undermine the therapeutic process.

AS WARD ADMINISTRATOR of a psychiatric inpatient unit, one of several in a psychiatric department that is part of a large university teaching hospital, I have developed a family-oriented inpatient service. This ward has managed to involve over 90% of the families of inpatients in the hospital treatment program using a variety of methods. This intensive involvement of families represents a new dimension for psychiatric hospitals and has consequently produced unique therapeutic problems. The details of how the inpatient staff attempts to change the family have been presented elsewhere.[1] In this paper the focus will be on how the family attempts to change the hospital staff and structure at the ward level, the department level, and the hospital administration level.

A review of the pertinent literature reveals a great deal of interesting work that unravels the intricate structure and function of psychiatric wards and mental hospitals (1-4). Most of these studies concluded that the hospital has a powerful influence on the behavior of inpatients. However, they did not focus to any significant degree on the interactions between the families of inpatients and the psychiatric staff. A few papers have discussed some of the transactions between families and psychiatric staff (5, 6). However, I am unaware of any literature that primarily focuses on the different mechanisms that families use to change the structure of hospital organizations.

In the hospital being discussed the clinical team with direct therapeutic responsibility for the family consists of the psychiatric resident (the team leader), members of the nursing staff, and the social worker. These people operate within a subsystem, i.e., the psychiatric ward of the hospital organization. The ward subsystem is constantly interacting with the other components of the hospital, and they are naturally influenced by any changes in the larger hospital complex. In the ward described here, the therapist (the psychiatric resident) of the identified patient is also the family therapist.

The family of a psychiatric patient entering the hospital is often in a crisis emerging from a chronic conflictive situation. Their usual expectation is that the hospital will take charge of and cure their sick member. They expect that this will be done with minimal effort on their part. When the hospital staff responds by placing certain therapeutic demands on the family, a unique and often stressful situation can arise. In addition, when the patient begins to change, it necessarily upsets the status quo of the family. The family must change to deal with these new influences.

As the family goes through these necessary changes, it may use a variety of mechanisms aimed at reestablishing a stable equilibrium. Some family members wish to prevent any modification of their internal structure, while others may hope to decrease the speed of the change process since they may fear consequent fragmentation. A mechanism frequently used is a maneuver by one or more family members aimed at influencing the behavior or attitudes of the therapist. As the therapist attempts to alter the patient's behavior by changing his or her most important interpersonal context (the family), the family will attempt to alter the context in which the therapist operates. This can mean the psychiatric ward, the department within which the ward exists, the overall hospital administration, or the sociopolitical agencies that control the hospital. One of the family's underlying h[illegible] that the therapist will withdraw his or her pre[illegible] change or modify the therapy for either t[illegible] patient or the family in such a way that t[illegible] continue to operate as usual (thereby m[illegible] stable equilibrium).

If the family is successful in significantly i[illegible] or gaining control of the treatment team, the [illegible] will find that he is operating in a system that l[illegible]

flexibility and freedom of action. This tends to lead to therapeutic failure because the family is then able to resist making necessary internal modifications of its individual members or of its own structure. Attempts by family members of psychiatric inpatients or by designated agents of inpatients to take control of the treatment process occur in many hospitals, but they seem to have been intensified and hence illuminated in the special ward discussed here. The struggles for control between hospitals and families usually take place covertly and are not often articulated by either group; yet the way in which a hospital staff manages these actions by the family is crucial to the therapeutic outcome.

Many different types of families use these mechanisms in order to avoid or minimize change. However, there are some common characteristics of the families that use these maneuvers most often. They can be categorized as follows: middle and upper socioeconomic class families, parents of adolescents and young adults, and families in which the patient has a fairly dramatic or disturbing problem, e.g., violent outbursts, psychotic and bizarre behavior, and suicidal behavior.

TRANSACTIONS AT THE WARD LEVEL

Families of psychiatric patients have the most contact with the ward staff, most frequently with psychiatric aides and least often with physicians and ward administrators. The most common type of maneuvering for control of the therapeutic process occurs at this level of the hospital organization. Some of the methods that families use include involving nontherapist staff members (e.g., the activity therapist or housekeeping personnel) in family disagreements, attempting to split the nursing staff from the physicians, forming coalitions with the lower administrative echelons (the aides) against the higher administrative echelons (the physicians or nurse chairman), forming coalitions with the higher administrative echelons against the lower echelons, and attempting to undermine the treating physician's authority by going over him to his supervisor, the ward administrator.

If successful, these actions can lead to fragmentation of the treatment team, thereby decreasing its efficiency as a therapeutic agent. The last maneuver is especially common; family members (usually the oldest or most authoritative) often appeal to the ward administrator for special treatment. Resistance to therapy can take many forms, one of which is to attack the credentials and status of the psychiatric resident who is the primary therapist.

> The father of one 19-year-old patient telephoned the ward administrator, apparently to obtain some data about a ward policy. Once his question was answered, he began to complain that he did not really understand the therapist's recommendations to the family. The father commented on the therapist's "foreign accent" and began to suggest that he was not a very competent p[illegible]. some discussion the crucial issue surfaced: [illegible] agreed with the therapist about the need f[illegible] to receive medication, and the father (who [illegible] fession related to medicine) wished to [illegible] over the prescription of medication to his [illegible] hoped to influence the supervisor of the [illegible] to intervene on his behalf in his daughter's [illegible]

Another common tactic is the formation of a negative coalition with the nurse and physician administrator of the unit, the highest echelon of the hospital bureaucracy, in order to undermine the authority of the psychiatric aide, the lowest echelon of the ward [illegible]

> A male attendant had set firm limits [illegible] the therapist) on a male teenage patient [illegible] ing out on the ward. The parents had [illegible] firm limits on their son at home and were [illegible] his complaints that the male attendant [illegible] abusive to him. The patient retracted [illegible] times and at one point said that he [illegible] theless, the parents, who were being [illegible] family therapist (who was also the boy's [illegible] more firm with their son, believed him [illegible] ward administrators fire the aide. The nurse [illegible] physician administrator were in an [illegible] cause they had two roles: that of supervisor [illegible] peutic team and head of the ward administration. [illegible] Their response was twofold: they would [illegible] charges, and if they found no evidence to [illegible] ent's view, they would attempt to limit [illegible] out behavior so that they could continue [illegible] therapy. They did this by trying to uncover [illegible] of the parents' anxiety, which was the [illegible] change the way they handled their son [illegible] necessitate a change in the internal structure [illegible]

Certain organizational characteristics of the administrative structure make it vulnerable to manipulation by the family. One of these is the hierarchical arrangements frequently found in the hospital. Henry (7) has described the hospital as having a particular kind of structure labeled multiple subordination: a type of structure in which personnel lower in the hierarchy have multiple supervisors setting clear-cut lines of authority. Henry points out that this type of structure often leads to chaos because of the contradictory splits in the directives given to subordinates. When [illegible] faced with conflicting messages from [illegible] sors, he or she may relinquish autonomy, [illegible] overly dependent or may withdraw and [illegible] her own structure autonomous from the [illegible] leadership. Indeed, this type of structure [illegible] on the ward level and can sometimes [illegible] deficits in communicational efficiency. [illegible] that this is similar to the kind of structure [illegible] that one observes in disturbed families. [illegible] treatment team usually attempts to establish [illegible] cut generational hierarchy in dysfunctional [illegible] and to prevent the kinds of conflicting [illegible]

two parents may be giving their offspring who is a psychiatric patient. Naturally, the ward staff's ability to change a family will be compromised if its own structure is fragmented and disjointed. A vicious cycle can be set up if the ward staff communicate contradictory messages to a family; it can encourage the family to respond with the kinds of self-protective maneuvers described in this paper, e.g., attempts to further split the ward staff.

TRANSACTIONS AT THE DEPARTMENT LEVEL

The next most frequent step that a family takes in order to decrease the pressure of changing its internal functioning is to go outside the ward level to someone higher in the department bureaucracy in order to have the ward staff alter its policies or therapeutic actions. This usually occurs when the ward staff has been successful in maintaining a cohesive unit that the family was unable to split. The most common object for influence is the next person in the administrative hierarchy, the director of all psychiatric inpatient units. Usually the family will call or see the director because of a seemingly legitimate complaint about the ward's policy, such as the need for the patient to stay longer in the hospital or some financial concern. There is often a covert message reflecting the family's fear of the types of changes that are occurring in their own structure. This can be due to either the direct influence of the family therapy or indirectly to the changes that the patient has undergone that necessitate a change in the family system. Sometimes the inpatient director refers the family back to the ward; at other times he may decide to allow the family to discuss the situation with him. If these moves are successful the family may calm down and continue to deal with their problems in the context of the ward's therapeutic approaches.

Another common tactic is for the family to contact a private psychiatrist affiliated with the department or a faculty member who knows the ward staff and ask him or her to intervene. Weintraub (8) has reported several cases of VIP patients whose private physicians were able to successfully intrude into the therapeutic freedom of the ward staff. The family described in the following vignette proved particularly resourceful in their attempts to mold the hospital bureaucracy.

> The patient was a 22-year-old schizophrenic woman in a symbiotic relationship with her parents. The upper middle class parents were accustomed to manipulating bureaucratic structures. They were initially reluctant to enter family therapy because they felt they were not a part of their daughter's problems; however, they finally agreed to participate. After a few weeks the mother announced that she needed more therapy than she was getting and said that she was engaging a private psychiatrist, who happened to be a senior psychiatrist in the department. This threw everyone including the ward administrator into confusion, since this person was a dominant figure in the administrative hierarchy. As everyone knew, this meant that the mother could potentially have a powerful ally outside the influences of the treatment team. The situation worked moderately well until a struggle ensued at discharge, with the family therapist making certain recommendations and the mother refusing to go along with them, saying that she had the agreement of her private therapist. Naturally, the family therapist (the psychiatric resident) was hesitant to challenge the mother given the chance that she was correct in interpreting her special alliance with the senior psychiatrist. Even though some clarification was eventually reached after the ward administrator contacted this psychiatrist, there was a certain amount of harm done to the family therapy work.

This example illustrates a weakness in the ability of a psychiatry department to remain unified vis-à-vis the family. This vulnerability is partly due to the presence of divisive ideologies among professional staff. In previous studies Strauss and associates (9) have identified three types of ideologies in the psychiatric profession: the psychoanalytic, the sociotherapeutic, and the somatic. They felt that these differences in professional ideologies can lead to considerable conflict and it is out of this arena that a specific treatment strategy emerges. In the above example there was a conflict of ideologies between the psychiatric resident (the professional subordinate in the administrative hierarchy) and the senior psychiatrist (the superior in the administrative hierarchy). The resident was operating from a sociotherapeutic ideology with a family emphasis and the senior psychiatrist from a psychoanalytic ideology, with the result that neither strategy could be carried out in a consistent and thorough manner.

HOSPITAL-LEVEL AND EXTERNAL SOCIOPOLITICAL AGENCIES

Families occasionally attempt to go beyond the ward or department level to the administrator of the general hospital. Others go even further—to such outside systems as the state or city government, the press, or the courts—in order to influence the therapeutic process. The organizational structure of the hospital is complex, and there are certain aspects that make it vulnerable to the actions of a small system such as the family. Smith and Kaluzny (10) have described several competing organizational models that are represented within health care institutions. Most important is the bureaucratic/industrial model and its conflict with the professional model. The conflict between these different types of organizational models leaves the hospital vulnerable to outside influences.

Family members may come to the hospital administrator complaining of the unavailability of a single room, impolite nurses, and so forth. The hospital administrators, who are usually operating under the corporate or industrial model, will probably react to the consumer complaint at face value and may see their responses necessary only in terms of maintenance of the organization. They may ignore what Smith and

Levinson (11) have called the instrumental functions of the hospital, which in this case would be the family psychotherapy. The physician/therapist, operating under the professional model, will stress the need for not allowing the family to act out and avoid changing itself. However, if the family is successful in forming a coalition with the hospital administrator, the professional and therapeutic goals may be minimized and lost.

Some families, after failing in their attempts to change the hospital structure, will go to social agencies that govern the hospital. The family in the following vignette was particularly successful in gaining control of the treatment team's attitudes in a very positive but powerful way.

> The wife was a psychiatric inpatient, and the husband was involved in marital therapy in the inpatient unit. At that time the air conditioning system was broken, and the husband (with some covert urging by the staff) decided to help the ward by trying to get it fixed. He had connections in the state governor's office and indeed managed to get the air conditioning system corrected (something that the ward administrator had been unable to do). The ward staff was extremely grateful for the husband's help. However, they had also become dependent on him because of his intervention, and this had the consequence of subtly limiting their ability to treat him as a patient.

Hysteria Split Asunder

BY STEVEN E. HYLER, M.D., AND ROBERT L. SPITZER, M.D.

The authors present the proposed DSM-III *classification of the traditional hysterical disorders, i.e., disorders that suggest physical illness but in which psychological factors are judged to be of importance. The use of the* DSM-III *inclusion and exclusion criteria—physical mechanism explains the symptom, symptoms are linked to psychological factors, symptom initiation is under voluntary control, and there is an obvious recognizable environmental goal—are discussed in the differential diagnosis of somatoform disorder, factitious disorder, malingering, psychological factors affecting physical condition, and undiagnosed physical illness.*

THE PROPOSED draft of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders (DSM-III)* presents a new classification for the diagnosis of disorders that suggest physical illness but in which psychological factors are judged to be of importance in the initiation, exacerbation, or maintenance of the disturbance. In *DSM-II* (1) many of these disorders were classified among the neuroses (e.g., hysterical, hypochondriacal, neurasthenic) or psychophysiologic disorders. In *DSM-III* conditions in which psychological factors are judged to be important, whether they are physical disorders, syndromes, or symptoms, are dissected and redefined according to certain fundamental distinctions. It is hoped that this will result in more reliable and valid diagnostic categories, not merely new theoretical explanations.

TRADITIONAL CONCEPT OF HYSTERIA

Traditionally the concept of hysteria included the following four criteria: the disturbance suggested physical illness, there were no demonstrable organic findings that explained the disturbance, there was positive evidence that the disturbance was linked to psychological factors, and the disturbance was not symptomatic of any other mental or physical disorder.

In the classical hysterical disorders an emotional conflict is converted into a physical symptom (hysterical conversion) that is considered a direct expression of the underlying conflict. Such disorders typically involve the voluntary nervous system and the sense organs. Among the most common classical hysterical conversions are paralysis, paresthesia, deafness, and aphonia.

In *DSM-II* the hysterical disorders were differentiated from the psychophysiologic disorders, which involved either a recognized physical disorder with demonstrable organic findings (e.g., bronchial asthma) or a physical symptom (e.g., sighing). In both cases the physical disturbance is caused by emotional factors.

The dichotomy between hysterical and psychophysiologic disorder seems to work well when the presentation is classical; it seems unlikely that anyone would make a mistake in the diagnosis of hysterical blindness or peptic ulcer. However, it is increasingly common to see atypical presentations in which these two categories are not adequate for describing the disturbance. Take the example of the person who seeks hospitalization by producing symptoms of physical illness, e.g., hematuria, by the deliberate ingestion of anticoagulants. It is clear that such a person has a diagnosable physical illness, yet the illness is initiated voluntarily. In the previous classification such a disorder would be forced into the classification of hysterical conversion, yet the nature of the disturbance has little to do with the strict definition of a conversion. Another example is the person who develops back pain as a consequence of an occupational injury and is thus unable to work. Even after the compensation issue is settled the patient continues to complain of pain, yet there is no known disease entity or mechanism that explains the bizarre pain the patient describes. What if it becomes obvious during therapy that the patient's husband is now attending to her "hand and foot"? What is this patient's diagnosis? What about the person who from an early age reports recurrent and multiple somatic complaints for which medical attention is sought but which are apparently not due to any physical disorder?

Revised version of a paper presented at the 131st annual meeting of the American Psychiatric Association, Atlanta, Ga., May 8–12, 1978.

At the time this work was done Dr. Hyler was a resident, New York Medical College, Metropolitan Hospital Division. He is now Research Psychiatrist and Dr. Spitzer is Chief of Psychiatric Research, Biometrics Research Department, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032. Dr. Spitzer is also Chairman, American Psychiatric Association Task Force on Nomenclature and Statistics.

TABLE 1
DSM-III Inclusion and Exclusion Criteria Used in the Differential Diagnosis of Symptom(s) Suggesting Physical Illness

Classification	Physical Mechanism Explains the Symptom	Symptoms Are Linked to Psychological Factors	Symptom Initiation Is Under Voluntary Control	Only [illegible]
Somatoform disorders	No	Yes	No	
Factitious disorders	Variable	Yes	Yes	
Malingering	Variable	Variable	Yes	
Psychological factors affecting physical condition	Yes	Yes	No	
Undiagnosed physical illness	Variable	Variable	No	

DSM-III CLASSIFICATION OF "HYSTERICAL" DISORDERS

Table 1 presents the *DSM-III* inclusion and exclusion criteria used in the differential diagnosis of mental disorders when the presenting symptom(s) suggest physical illness.

"Physical mechanism explains the symptom" means that either the symptoms represent an accepted and diagnosable physical disorder or syndrome (e.g., angina pectoris, duodenal ulcer, epilepsy) or that there is a specific pathophysiological mechanism that explains the symptom (e.g., vasovagal reflex for fainting, muscle tension for tension headache, muscle spasm for backache).

"Symptoms are linked to psychological factors" indicates that the clinician believes that there is a recognizable temporal relationship between the presence of specific psychological factors or an emotional conflict and the onset or regular occurrence of the physical symptom. Often the individual may not be aware of the role of psychological factors. An example is the individual who becomes nauseated and vomits regularly prior to sexual intercourse.

"Symptom initiation is under voluntary control" means that either the individual simulates the symptom, e.g., feigns the typical pain of a myocardial infarction, or initiates the process that results in the physical symptom, e.g., takes crystalline sodium warfarin (Coumadin), which leads to hematuria. The fact that the individual may claim that he or she cannot refrain from engaging in the behavior that initiates the physical symptom does not rule out its voluntary production. Although the individual may deny the voluntary production when confronted with evidence of such behavior, the clinician is justified in assuming voluntary production because of the nature of the presentation. The accidental production of symptoms is usually ruled out by the repeated occurrence of the symptoms.

"Obvious recognizable environmental goal" indicates that the examiner must make the determination as to whether the symptom production is in pursuit of a goal that is obviously recognizable, using a knowledge of the environmental circumstances rather than the individual's psychology. Examples of such goals include monetary compensation, evasion of justice, and avoidance of conscription. These are obvious and recognizable goals to any layman. In di[illegible] that only become apparent with a [illegible] individual's psychology include expr[illegible] rental substitutes, satisfying unmet d[illegible] and playing the role of a patient to s[illegible] impulses. These goals are understa[illegible] pretable only by the trained clinician.

SOMATOFORM DISORDERS

The somatoform disorders include [illegible] orders that have been classified as hy[illegible] in this category is somatization (Br[illegible] which is a chronic but fluctuating dis[illegible] early in life and is characterized by rec[illegible] tiple somatic complaints for which m[illegible] sought but that apparently are not du[illegible] disorder. The complaints refer to m[illegible] tems, e.g., abdominal pain with vom[illegible] aches, joint pain, and menstrual abn[illegible] tization disorder has been removed f[illegible] of hysterical personality because it ha[illegible] individuals with a lifelong pattern of s[illegible] for multiple somatic complaints d[illegible] have a hysterical, i.e., histrionic, per[illegible] versa (2, 3). When these two disorder[illegible] ommended that both diagnoses be m[illegible]

Conversion disorder has also been [illegible] the category of hysterical personality [illegible] been noted that persons with other p[illegible] orders, or with psychoses, may unde[illegible] tions manifest conversion symptoms [illegible] version disorder the predominant fe[illegible] alteration in functioning that suggest[illegible] but which is actually a direct expres[illegible] logical conflict that is not under volu[illegible] not explainable on the basis of a kno[illegible] mechanism. The most common conver[illegible] are those that suggest disorder of the v[illegible] vous system or the sense organs, e.g. pa[illegible] nia, and seizures. This disorder shoul[illegible] nosed when the clinical picture is part o[illegible] vasive somatization disorder or when t[illegible] are limited to sexual dysfunction, which is [illegible] rately. This disorder replaces the *DSM-I* [illegible] hysterical neurosis, conversion type.

The third disorder in this group is p[illegible]

predominant feature of which is the complaint of pain not associated with any physical condition or explained by any pathophysiologic mechanism. Psychological factors are judged to be important in the initiation, exacerbation, or maintenance of the pain. The pain follows no neurological distribution and may present a bizarre pattern. This disorder has been removed from the category of hysterical conversions, in which pain is the presenting symptom. Because this is a new diagnostic category, its validity has not yet been established. It is recommended that extreme care be used in making this diagnosis. Many persons who have been described as having compensation neurosis may now be classified in this category. An example of this is the individual who, even after a monetary compensation issue has been settled, continues to experience and complain of pain when there is no evidence of a physical disorder, syndrome, or mechanism to account for the pain. Persons whose complaints of pain disappear soon after settlement of a compensation issue may best be classified as malingerers.

The fourth disorder in this group is hypochondriasis (6). Its predominant feature is the individual's fear that he or she may have a disease. This fear is refractory to simple reassurance, and the person often goes "doctor shopping" until he finds a physician who can make the appropriate diagnosis. This disorder is differentiated from somatization disorder in that the individual's fear that he may have a disease, rather than multiple somatic complaints, is predominant. In hypochondriasis the complaints are usually more circumscribed. This category may be used for patients who were previously described as having cardiac neurosis, and who have a preoccupation with cardiac symptoms, or cancer phobia, and who may interpret minor aches and pains as evidence of neoplasm.

FACTITIOUS DISORDERS

An entirely new diagnostic category in *DSM-III* is factitious disorder, which was included to fill the large middle ground between the hysterical disorders and malingering. "Factitious" means not real, genuine, or natural and describes that which is produced by art or design. Factitious disorders are therefore characterized by physical or psychological symptoms that are voluntarily initiated by the patient. This differentiates the factitious from the somatoform disorders. The factitious disorders are also differentiated from malingering. In cases of malingering the patient also produces symptoms voluntarily but they are for a goal that is obviously recognizable with a knowledge of the environmental circumstances. In factitious disorders there is often no apparent goal other than to assume the role of a patient. In time it may become apparent that such a patient is attempting to gain mastery over a previously experienced psychic trauma or is acting out a sadomasochistic relationship with physicians who are regarded as parental figures, but these are considered individual goals that are related to the patient's psychology. In addition, whereas under certain circumstances an act of malingering may be considered adaptive, as in the hands of the enemy during a war, a diagnosis of factitious disorder always implies severe pathology that is usually indicative of an underlying personality disturbance. The factitious disorders are subdivided depending upon whether the symptoms presented are psychological or physical.

In the subcategory of factitious illness with psychological symptoms the essential feature is the voluntary production of symptoms suggestive of a mental disorder, in the absence of an obvious recognizable goal. The mental symptoms are usually a representation of the person's conception of what a mental disorder should be rather than being indicative of any specific diagnostic category. This disorder subsumes former diagnoses such as hysterical Ganser syndrome (7), pseudopsychosis, and some cases of pseudodementia (8). The individual with this disorder is often recognized by the pansymptomatic complex of mental symptoms that is presented, e.g., memory loss, visual and auditory hallucinations, approximate answers, and not being able to recognize the color red. This disorder is very difficult to differentiate from malingering. Often a combination of recognizable environmental goals coexists with recognizable psychological goals. An example of this is the patient with a schizophrenic disorder who upon learning that he is to be discharged presents a bewildering array of new and bizarre symptoms. If it is thought that psychological factors (such as a dependency on the hospital) rather than environmental factors (such as an absence of a place to live) are instrumental in the production of the new symptoms, then the symptoms should be considered factitious and superimposed on the original schizophrenic disorder. The validity of this disorder when not associated with any other mental disorder remains to be established.

The next subtype is chronic factitious illness with physical symptoms (9), often referred to as the Munchausen syndrome (10). The essential feature is the patient's plausible presentation of factitious physical illness of such a degree that he is able to obtain and sustain multiple successive hospitalizations. The symptoms described are limited only by the patient's medical knowledge, sophistication, and imagination. Other synonyms have included hospital addiction syndrome (11), hospital hoboes (12), and peregrinating problem patients (13).

Associated features of this disorder include pseudologia fantastica, an extensive knowledge of hospital routines (which improves with each new hospitalization), analgesic abuse, and "gridiron abdomen" from multiple surgical procedures. This disorder is thought to be extremely incapacitating and is apparently refractory to any type of therapy. This category was created to facilitate the recognition of such patients, who clearly have serious psychopathology not classifiable in *DSM-II*. In the past such patients have

been diagnosed as having schizophrenia, antisocial personality, hysterical personality, and hysterical neurosis, conversion type. Should these patients meet the criteria for any other mental disorder, both diagnoses should be made.

Other factitious illness with physical symptoms is a residual category for individuals with factitious physical symptoms who do not meet the criteria of the better-studied, more pervasive disorder mentioned above. The patient may not seek hospitalization but may appear at an outpatient department with a dermatitis artefacta or a voluntary dislocation of the shoulder.

It should be emphasized that the presence of a factitious disorder with physical symptoms does not necessarily imply the absence of organic pathology. Many times the individual is very ill indeed, and almost any of the self-inflicted traumas results in true physical pathology. It is the initiation of symptom production that is factitious.

CATEGORY 316

Category 316, psychological factors affecting physical condition, is also a new category in *DSM-III*. It subsumes the *DSM-II* category of psychophysiologic disorders but is broader in scope. Here the clinician notes those physical conditions for which he believes psychological factors are important in the initiation, exacerbation, or maintenance of the condition. The clinician is further requested to specify the certainty that he believes the psychological factors are contributory as either probable or definite. The physical condition is coded separately on axis III. An example of the use of this diagnostic category would be to indicate the suspected importance of psychological factors in such diverse disorders as bronchial asthma, angina pectoris, tension headache, syncope, or nausea and vomiting. A more detailed discussion of this category is available elsewhere (14).

UNDIAGNOSED PHYSICAL ILLNESS

Given the present state of the art of medical diagnosis and limitations in objective diagnostic laboratory tests, it is a common occurrence that a person may manifest certain physical symptoms for which no diagnosis of either physical or mental disorder can be made. The physical complaints should not be classified in any of the aforementioned disorders unless the newly established criteria are met. For example, a person may have weakness, tremors, and paresthesias. If all diagnostic tests are negative or equivocal, if it is thought that the symptoms are not under voluntary control, if there are no obvious recognizable environmental goals, and the examiner does not have positive evidence that the symptoms are linked to psychological factors, the possibility of an undiagnosed physical illness should be considered. A number of [illegible] orders, e.g., cortical blindness or extrapy[illegible] ease, may be mistaken for hysteria (15). [illegible] been shown that when a number of patie[illegible] been given diagnoses of hysteria were fo[illegible] time, they developed full-blown medical c[illegible] ulcerative colitis or multiple sclerosis (16).

Mention should be made of two othe ca[illegible] have in the past been considered as hyster[illegible] physical symptoms may not have been [illegible]

BRIEF REACTIVE PSYCHOSIS

In brief reactive psychosis the essenti[illegible] a florid psychosis of at least a few hou[illegible] lasting not more than one week, with [illegible] immediately after severe emotional s[illegible] tually terminating in complete recov[illegible] psychotic state. This disorder is des[illegible] cause it has been informally referred to [illegible] psychosis, and some patients given the [illegible] nosis of acute schizophrenic episode w[illegible] classified here. Despite its occasional [illegible] similarity to a schizophrenic disorder (e[illegible] hallucinations), the distinction is impo[illegible] the course and prognosis are different

HISTRIONIC PERSONALITY DISORDER (HYSTERICAL PERSONALITY)

Here the essential feature is a patter[illegible] behavior that is overly reactive, intense[illegible] and perceived by others as shallow, sup[illegible] sincere, with characteristic disturbed [illegible] relationships. This personality disorde[illegible] trionic" rather than "hysterical" to em[illegible] trionic mode of presentation and to remov[illegible] tive connotation to women (4, 5) (and any[illegible] to the uterus). The occurrence of this diso[illegible] is well recognized (17).

DISCUSSION

The differentiation between "real" [illegible] terical" symptoms has been among the [illegible] diagnostic tasks for physicians. Not on[illegible] been the problem of establishing what s[illegible] toms are without physical basis, but th[illegible] been the problem of how to classify the [illegible] order, its causes, the course, the prog[illegible] appropriate therapy. The purpose of recla[illegible] terical disorders was to maximize the [illegible] the diagnosis for the outcome and select [illegible] priate therapy. It is expected that the [illegible] individual with a somatoform disorder wi[illegible] at the psychological component, which is [illegible] etiologic, rather than at the overt physi[illegible]

that are presented. In factitious disorders it is expected that the liaison psychiatrist will be able to recognize the etiologic psychological factors that are often hidden by the dramatic presentation of acute physical illness. Psychiatrists should attempt to educate physicians of other disciplines in the recognition of such patients so as to avoid needless, costly, and dangerous somatic procedures and operations. Perhaps in the future an effective type of psychiatric therapy will be developed for this condition. A diagnosis of category 316 will usually require the cooperation of the psychiatrist and the physician who is treating the physical condition and appropriate coordination of therapy directed at the physical and psychological components.

In creating new diagnostic categories for hysteria in *DSM-III* it was decided that all that is not genuine is not the same. It is hoped that the distinctions will prove useful.

TOPICAL PAPERS: Psychiatric Residency and Clerkship

Group Therapy Training in Psychiatric Residency Programs
A National Survey

BY EDWARD L. PINNEY, JR., M.D., STEPHEN H. WELLS, PH.D., AND BERNARD FISHER, PH.D.

The authors used a questionnaire sent to the directors of the 256 approved American psychiatric residency programs to examine the availability, content, and orientations of group therapy training. They found that 78% of the responding programs offered group therapy training, a substantial increase from earlier estimates; that an approach incorporating didactic courses, observation and leadership of groups, supervision, and participation in an experiential group was gaining increased acceptance; that most of the programs provided a variety of arrangements for supervision of group training; that the theoretical orientations mirrored the field of group therapy itself; and, finally, that associated disciplines were gaining increasing acceptance.

INCREASING RELIANCE on group treatment approaches has been characteristic of the psychiatric scene over the past three decades, closely paralleling the development of the small group movement in the country at large. Although considerable interest has been generated by the profusion of what many regard as new, effective, and economical techniques, the number of warnings about leadership competency has been growing. In a 1970 task force report (1), the American Psychiatric Association decried the "extraordinary heterogeneity" among group leaders, therapists as well as others, in levels of competence, skills, discipline, goals, and motivations. If this statement has substantial merit, examination of the training experiences of professionals who practice as group therapists is a matter of some urgency.

Although psychiatry has not generally been in the leading force among the mental health disciplines in the advancement of group therapy, psychiatric residency programs patently represent the single most significant training source of practitioners in this area. Relatively meager data are available, however, on the nature and extent of group therapy training offered in residency programs. Based on a 1950 questionnaire survey of residents at 14 centers, Ward (2) reported that only one-third of trainees in his sample had the opportunity to participate in or practice group therapy. When Ward and Kaplan (3) repeated the survey in 1961 for purposes of historical comparison, exposure to group therapy training was found to have increased to 72% of the residents at the psychiatric centers. Both survey reports strikingly underscored residents' enthusiasm for the modality: group therapy emerged in each study as "most valued" by those who had experienced it and as "most desired" by those who had not been afforded the opportunity.

In 1971 Sadock and Kaplan (4) estimated that group therapy training was provided to residents in 60% of the existing programs. Although this figure may have been somewhat on the low side, the factors they cite to account for the relative paucity of opportunities observed in 1971 are quite accurate: a dearth of qualified training faculty, time constraints of the residency schedule, resistance to a new and unfamiliar

At the time this work was done, Dr. Pinney was Clinical Associate Professor of Psychiatry, Department of Psychiatry, Cornell University Medical College, New York, N.Y., where Dr. Wells is Clinical Instructor of Psychology in Psychiatry, and Dr. Fisher is Associate Professor of Psychology in Psychiatry. Dr. Pinney is now Clinical Associate Professor of Psychiatry, New York University Medical Center. Address reprint requests to him at P.O. Box 460, Gracie Station, New York, N.Y. 10028.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

and prejudice against a "secondary" or "inferior" technique.

The present study sought to provide a comprehensive and contemporary picture of group therapy training in approved residency programs. To that end, a national survey was performed in which the availability, content, and orientations of group therapy training in these programs were examined.

METHOD

A survey questionnaire was mailed to the program directors (or chiefs of service) of the 256 approved psychiatry residencies listed in the 1975–1976 *Directory of Approved Residencies* of the Liaison Committee on Graduate Medical Education of the American Medical Association (5). These programs included 196 residencies affiliated with university teaching hospitals and 60 unaffiliated residencies.

The questionnaire was a brief survey form that requested the following information[1]: 1) availability of training in group psychotherapy for psychiatric residents, 2) postgraduate year(s) during which group psychotherapy training was available, 3) training for members of other professional groups, 4) the types and relative importance of training techniques used, 5) whether residents worked alone with groups or with a cotherapist, assistant therapist, or observer-recorder and the profession of the cotherapist, assistant therapist, or observer-recorder, 6) the theoretical orientation of group psychotherapy training, and 7) the type and focus of supervision of trainees.

A total of 172 of the 256 mailed questionnaires were returned, giving a response rate of 59.3%. Responses were received from 138 of the affiliated and 34 of the unaffiliated residency programs.

RESULTS AND DISCUSSION

Resident Access to Group Therapy Training

Residents in 135 of the 172 programs reporting (78.5%) had access to group therapy training during at least one of their postgraduate years (see table 1). Only 37 of the programs (21.5%) offered no such experience to their trainees. Although the results of the earlier surveys discussed above (2, 3) are not directly comparable to the results of this study, there would appear to be little doubt that the acceptance of group therapy in residency training programs has increased.

Even more striking than our finding that 4 of the 5 programs we surveyed included group therapy training are the findings with regard to duration and extensiveness of the experience offered. The most prevalent arrangement, representing more than one-third of the cases, was one in which the resident participated during postgraduate years 2 to 4 inclusive. Approximately 62.2% of the programs (N=107) offered group therapy training over 3 or 4 postgraduate years, and in only 16 (9.3%) of the programs was the resident's introduction to the modality delayed until postgraduate year 3.

This development is of great importance for group therapy training. It has long been recognized that starting group therapy training as early as postgraduate year 1 would enhance the trainee's overall level of interpersonal awareness in such a way as synergistically to augment functioning in other therapeutic modalities. Early exposure, as Sadock and Kaplan (4) noted, also serves to forestall the development of prejudices toward group therapy on the part of the resident, since he or she comes to regard it as an accepted component of residency training rather than as a secondary and auxiliary mode of treatment.

An efficacious personal impact on the resident may also be observed as a consequence of experience in group therapy and in related trainee groups and supervisory triads or groups. All these can assist the resident in gaining greater confidence and effectiveness in

the group settings and interpersonal situations that are inevitably part of professional life.

Group Training Modalities Employed

Table 2 presents the survey findings on modalities used for the teaching of group therapy in the residency programs. It is clear that the use of multiple training modalities has gained ascendency; 126 of the programs (93.3%) used more than one training technique. The primary training pattern, used by nearly one-half of the programs, included didactic seminars or lectures, live observation of groups, and participation in an experiential group (in addition to some form of supervision, which every program incorporated). It is not surprising that supervision was a feature of each of the programs and that all but 5 included a didactic seminar or lecture component. What is striking is the extent to which program directors recognized the need for participation in experiential groups. More than three-quarters of the programs provided groups in which the resident participated as a member rather than a leader.

A comparison of the survey findings with the training model proposed by the American Group Psychotherapy Association (AGPA) in 1970 (6) is instructive. The AGPA guidelines call for didactic courses and case seminars, observation and leadership of at least three therapy groups, supervision, and participation as a member in a group psychotherapy or group training experience. This model is finding increasing acceptance in residency training programs.

Patterns of Supervision

As previously reported, every residency program offering training in group therapy provided supervision in some form to its trainees. The possible supervision arrangements examined in this survey included individual or dyadic (one supervisor with one group therapist), triadic (one supervisor with two trainees who worked as cotherapists), and group (one supervisor with several group therapists) supervision. As table 3 indicates, more than 80% or 110 of the programs had flexible arrangements in which two or more of these variants could be employed. Within this group, the predominant model was to permit the use of all three supervisory patterns.

The most conventional arrangement, derived from earlier experience in the supervision of individual psychotherapy, is the dyadic. In the view of some (7), however, the triadic pattern has greater efficacy for group therapy. The triadic supervisory process permits the examination not only of events within the group but also of the relationship between the cotherapists, both as it manifests itself within the group and as it emerges in the context of supervision. We found that the triadic was the most often employed of the three models, as shown in table 3.

Group supervision provides still further possibilities for training. The several trainees themselves constitute a group, the dynamics of which can be explored to elucidate aspects of the residents' group and interpersonal experiences, particularly with regard to countertransference. There is a likelihood, in the view of Marohn (8), that under such conditions "the themes of the formal therapy with patients" will be "similar to the themes of subsequent supervisory meetings." We found that group supervision was employed by fewer centers than either of the other patterns, a phenomenon probably due, at least in part, to the highly challenging nature of such work for the supervisor.

2, 3, and 4	32
1, 3, and 4	26
3, 4, and 5	11
Other combinations	9

Theoretical Orientations of Group Training

Table 4 presents data on the theoretical orientations of the 135 residency group therapy training programs. The compiled findings are striking in the extent of pluralism portrayed. Fully 90% of the programs (N=122) described their orientations as a combination of two or more theoretical viewpoints. A group process orientation was the single most frequently cited theoretical stance, cited in 118 (87.4%) of the programs. The most frequent combination of orientations, presented by more than one-third of the responding programs, incorporated psychoanalytic, interpersonal, group process, and group dynamics theories.

It is not inconceivable that the prevalent

bined orientations indicates that many of the programs used a well conceived and carefully elaborated combination of approaches. A more likely conclusion is that the survey findings precisely mirror the situation in the group therapy field itself. Throughout its history, as Peck (9) observed, there has been a "plaintive and continuing call for a more definite conceptual framework for group psychotherapy." That the call has not yet been answered may reflect deficiencies in the work done. On the other hand, it may express certain special difficulties inherent in the task of bringing psychodynamic, group-focused, and social change perspectives to bear in the developing role of the group therapist.

Training of Associated Disciplines

Given the significant role of such associated disciplines as psychology and social work in the development of group therapy, it is interesting to examine the extent to which residents have contact with other professionals in the course of their group training. Based on examination of the survey data presented in table 5, it is clear that such contact is more extensive than might have been anticipated. Fully 82% or 111 of the programs offering group therapy training to their residents permitted the participation of trainees from at least one other discipline. Clinical psychologists and social workers were, not unexpectedly, the most frequently included professional groups, each being represented in more than 3 of 5 reporting programs. Although no other group achieved such "penetration," a broad range of disciplines found representation.

Findings on the arrangements under which psychiatric trainees function as cotherapists in the group therapy programs show that the predominant pattern, reported for 69.6% or 94 of the centers, was one in which residents worked with each other; however, in more than half of the programs they also trained as cotherapists with psychologists, social workers, and psychiatric nurses.

Ward and Rickels (3) reported a striking decrease in residents' contacts with associated disciplines between their 1950 survey and the one undertaken in 1961. Two-thirds of the residents in 1961 had little or no such experience. Quite clearly a very different situation exists for residents who participated in group therapy training in 1977.

TABLE 5
Inclusion of Other Professionals in 135 Group Psychotherapy Training Programs for Psychiatric Residents

Item	Programs	
	Number	Percent
Professional group		
Clinical psychologists	89	65.9
Social workers	83	61.5
Psychiatric nurses	69	51.1
Occupational and related therapists	37	27.4
Paraprofessionals	29	21.5
Others	8	5.9
Total programs including other professionals	111	82.2
Total programs with no others included	24	17.8

There is considerable sentiment within psychiatry favoring the inclusion of other mental health professionals as coequal faculty members and trainees in medical centers. Group therapy training programs appear to embody this sentiment, operating as distinctively open environments within the residency context. The very diversity, complexity, and richness of group therapy itself apparently serves to promote recognition of the need for varied perspectives in its teaching.

Consultation-Liaison Versus Other Psychiatry Clerkships: A Comparison of Learning Outcomes and Student Reactions

BY WILLIAM W. WEDDINGTON, JR., M.D., FREDERICK R. HINE, M.D., JEFFREY L. HOUPT, M.D., AND CAROLE S. ORLEANS, PH.D.

The authors present the results of a one-year study showing equivalent mastery of basic psychiatric knowledge and skills and equally favorable student reactions after psychiatry clerkships on a consultation-liaison service and on other more traditional psychiatry services. They recommend further research highlighting the unique contributions of consultation-liaison clerkship training to knowledge, skills, and attitudes for holistic primary care.

RECENT DEVELOPMENTS have formalized the demand that all physicians be capable of providing holistic care for their patients—care that includes competence in the behavioral sciences and clinical psychiatry (1). Developments at the national and local levels have combined to give force to that demand. They include the *Report of the Citizens' Commission on Graduate Medical Education* (2) detailing the required areas of competence for primary care physicians, the priorities of the National Institute of Mental Health Psychiatry Education Branch favoring support for educational programs that demonstrate collaboration between psychiatry and general medicine (3), and local medical school policies fostering productive relationships between psychiatry and other departments.

As one outgrowth of these developments, increasing numbers of medical students are receiving training in consultation-liaison psychiatry (4). In addition, consultation-liaison services have been recommended as favored settings for psychiatry clerkship training (5).

At the time this work was done Dr. Weddington was a resident, Department of Psychiatry, Duke University School of Medicine, Durham, N.C., where Dr. Hine is Professor and Director of Medical Student Training in Psychiatry, Dr. Houpt is Associate Professor and Chief of Consultation-Liaison Services, and Dr. Orleans is Assistant Professor of Medical Psychology. Dr. Weddington is now Assistant Professor of Psychiatry, Pritzker School of Medicine, University of Chicago, Chicago, Ill. The training programs described in this paper were supported in part by Alcohol, Drug Abuse, and Mental Health Administration training grants MH-05972 and MH-07435 from the National Institute of Mental Health.

The authors wish to acknowledge the statistical consultation of William Cleveland, Ph.D.

Because they ensure direct contact with patients whose needs and symptoms closely approximate those which most students will encounter in their own patients, it has been argued that clerkships on a consultation-liaison service will facilitate the learning of psychiatric knowledge and skills and thereby contribute to more holistic future patient care. Moreover, since core experiences on consultation-liaison services involve primarily surgical, medical, and gynecological patients, whereas psychiatric clerkship training has traditionally occurred in psychiatric settings where patients are identified as psychiatric patients under psychiatric supervision, psychiatric educators might appropriately wonder whether consultation-liaison clerkships really provide adequate basic knowledge and skills.

To address this issue the present study compared students clerking on a consultation-liaison service with students clerking on more traditional inpatient and outpatient psychiatry services. Two questions were asked: Do students on a consultation-liaison clerkship acquire sufficient psychiatric knowledge and skills, and do they rate their clinical training experiences as favorably as students on traditional psychiatry clerkships?

METHOD

The subjects consisted of 106 second-year Duke University Medical School students who had previously completed a first-year psychiatry-behavioral science course and were enrolled in the required psychiatry clerkship during the 1975–1976 academic year. (Under the Duke curriculum, students complete required clinical clerkships during their third year.) Fourteen students completing their clinical clerkships on the psychiatry consultation-liaison service were compared with 92 students who clerked on traditional inpatient and outpatient psychiatry services.

Postclerkship knowledge of traditional psychiatric concepts and techniques was determined from special administrations of the National Board of Medical Examiners' part II psychiatry examination. Findings on signed course-evaluation questionnaires provided four measures of student reaction to clerkship training and instruction. Students rated their "overall learning experience on the service" and "adequacy of supervision and teaching" on

0002-953X/78/0012-1509$0.45 © 1978 American Psychiatric Association

and senior staff" and the contributions of a Multidimensional Psychiatric Diagnosis and Treatment (MPDT) program (described below) to improving their 3) "interactional skills and interviewing techniques," and 4) "understanding of psychiatric concepts and techniques as they apply to nonpsychiatric patients." Student ratings, which remained sealed until after grades were determined, were obtained using 5-point rating scales with the following anchor statements: 1="poor, not worth the time"; 2="unsatisfactory, mediocre"; 3="fair, useful"; 4="good"; and 5="excellent, outstanding."

Because the clerkship comparison groups were constituted through self-selection rather than random assignment, preclerkship measures were used to control for selection factors that might affect training outcomes (6). Students' numerical grades on a written take-home examination administered after the behavioral science course in the previous year constituted a single measure of preclerkship psychiatric knowledge.[1] Ratings of the first-year course, which also remained sealed until after first-year grades had been submitted, were obtained using the same 5-point rating scales employed for clerkship ratings. A measure of student reaction to preclerkship psychiatry training was obtained by averaging student ratings of the adequacy of the course to "introduce concepts and techniques of interviewing," "communicate behavioral science concepts and their importance to medicine," and "demonstrate the approach of the behavioral scientist." Ratings of the "general teaching effectiveness of small group instructors" provided a measure of student reaction to preclerkship psychiatry instruction.

Description of Psychiatry Clerkship and Human Behavior Courses

The second-year clinical psychiatry clerkship is one of five 8-week, full-time required clerkships. Students request assignment to one of the following six basic services: Duke Hospital Consultation-Liaison Service, Duke Hospital Inpatient Service, Durham Veterans Administration Hospital Inpatient Service, John Umstead (State) Hospital Inpatient Service, Duke Hospital Psychiatric Outpatient Clinic, and Durham Child Guidance Clinic. Assignments are based on students' requests except when a particular service is oversubscribed; in those cases students are usually assigned second- or third-choice services.

Students assume clinical responsibilities under the primary supervision of a resident and under more general supervision from senior faculty. They work up and follow patients according to the program used on their service and attend work rounds and case conferences with residents. Students on the consultation-liaison service work primarily with surgical, medical, and obstetric-gynecological inpatients, while students on other psychiatry services work primarily with identified psychiatric inpatients or outpatients. All students on noninpatient units (consultation-liaison, adult and child psychiatric outpatient) evaluate inpatients one half-day per week at John Umstead Hospital to gain experience with more severe forms of psychopathology.

In addition to rotations through basic clinical services, all clerkship students participate in two common core activities: didactic lecture-seminars on such topics as psychiatric diagnosis and treatment modalities, and the MPDT program, designed to increase students' understanding of the value and importance of psychiatric concepts and techniques in medicine generally. The MPDT program, described in detail elsewhere (7), begins with lecture-seminars in which psychiatric diagnoses are presented as dimensions that may be present in severe degrees, as in psychiatric illness, or in mild or moderate degrees, as may be found in the population generally and medical-surgical patients in particular. After this introduction students interview patients randomly selected from nonpsychiatric hospital services, tape these interviews, and receive detailed one-to-one supervision from members of the psychiatry staff.

Students also share a common preparation for clerkship training. All students take a first-year psychiatry behavioral science course that combines 60 hours of lectures on behavioral neurobiology, medical sociology, human development, psychodynamics, and communication processes with small group sessions directed at extending lecture material and providing experiential training in interview techniques.

TABLE 1
Preclerkship Measures of Students' Psychiatric Knowledge and Ratings of First-Year Psychiatric Training and Instruction

* p<.05, two-tailed t test, df=104.

for each of the five single traditional clerkship groups, and for the larger traditional psychiatry group consisting of all students clerking on the five combined traditional psychiatry services. To determine whether students could be significantly differentiated on the basis of clerkship services, one-way analyses of variance were performed on the scores of the consultation-liaison group and of the five single traditional clerkship groups, yielding a single F value for each measure. To compare students in the consultation-liaison group with students in the larger traditional psychiatry group, t tests were performed on the mean scores of both groups, yielding a single t value for each measure.

Table 1 presents the means and F and t values for preclerkship measures of psychiatric knowledge and student ratings of first-year psychiatry training and instruction. As can be seen from the table, none of the scores of the preclerkship measures were significantly differentiated on the basis of clerkship service (F values<1, df=5, 100, n.s.). Further, separate t tests revealed that students clerking on the consultation-liaison service did not differ significantly from those clerking on the combined traditional psychiatry services (t values<1, df=104, n.s.) with respect to any of the measures obtained before clerkship training.

As can be seen from table 2, the analysis of variance on National Board psychiatry scores, with means of 511.43–573.89, revealed that the type of clerkship service had no significant overall effect on students' scores. Further, the t test revealed that the National Board scores of students clerking on the consultation-liaison service did not differ significantly from those of students clerking on the combined traditional psychiatry services.

As can also be seen from table 2, analyses of variance on ratings of service training, with means of 3.86–4.29, and ratings of service instruction, with means of 3.76–4.40, revealed that the type of clerkship service had no significant overall effect on students' reactions to their clerkship experiences. Further, separate t tests revealed that the ratings of students clerking on the consultation-liaison service did not differ [illegible] from those of students clerking on the combined traditional psychiatry services.

Finally, table 2 shows that the analyses on ratings of MPDT contributions to interviewing skill (MPDT 1) and to understanding the role of psychiatry in medicine (MPDT 2), with means of 3.[illegible]–3.29–4.03, respectively, revealed that [illegible] clerkship service had no significant overall effect on students' reactions to the MPDT program. However, separate t tests revealed that students clerking on the consultation-liaison service rated the MPDT program as contributing significantly less to their interviewing skill (t=2.25, df=104, p<.05) and to their understanding of the role of psychiatry in medicine (t=[illegible], df=104, p<.05) than did students clerking on the combined traditional psychiatry services.

COMMENT

The results of our investigation suggest that students who clerk on a consultation-liaison service receive more traditional psychiatry services and participate in a common core curriculum acquire [illegible] knowledge of basic psychiatric concepts and techniques. In addition, our findings suggest that consultation-liaison clerkship students value psychiatry experiences as highly as do students clerking on other services.

The finding of equivalent learning outcomes extends previous findings (5) showing consultation-liaison clerkship students to perform as well on a comprehensive psychopharmacology exam as students on traditional psychiatry services, by using the nationally standardized National Board of Medical Examiners' psychiatry exam, and by demonstrating no significant preclerkship differences that might affect interpretation of uniform postclerkship knowledge. The present findings are also consistent with those of a recent study (6) showing no significant differences on [illegible]

Board part II exam and objective exams among students clerking on five different psychiatry inpatient services. In this and the previous study (8), it is likely that standardized didactic instruction offered before and during the clerkship contributed to uniform outcomes in formal knowledge.

The present study, unlike a previous study (4), does not show that consultation-liaison clerkship experiences are valued more highly than more traditional clerkships. The unexpected finding that MPDT training was rated as less valuable by consultation-liaison students, who saw primarily nonpsychiatric patients, than by clerkship students, who saw primarily identified psychiatric patients, is probably due to real and perceived overlap in consultation-liaison and MPDT experiences. While the random selection of patients in the MPDT program was designed to demonstrate the relevance of psychiatry to all medical-surgical patients, many patients reviewed on the consultation-liaison service were similar in that they did not have obvious psychiatric illness and would probably not have been referred for psychiatric consultation. In addition, MPDT and consultation-liaison instruction and supervision were similar in focusing on the role of psychiatry in medicine. Against this background it is possible that the unique contributions of the MPDT program, such as detailed process supervision, were less salient for consultation-liaison than for other clerkship students. Moreover, questionnaire items were not specifically designed to bring into sharp focus unique benefits of MPDT over consultation-liaison experiences.

The present study examined only whether consultation-liaison clerkship experiences were as adequate to impart basic psychiatric concepts and techniques as more traditional psychiatry clerkship experiences. Using both National Board exam scores and student ratings of the quality of training, it was demonstrated that consultation-liaison students are not placed at a disadvantage relative to students clerking on inpatient and outpatient psychiatry services. Given continued federal support for the development of consultation-liaison training programs and the likelihood that consultation-liaison services will be increasingly used for clerkship training (4, 5), the time is now ripe for research that replicates and extends these and previous (5) findings. Specifically, we recommend further research exploring the unique contributions of consultation-liaison clerkship training to the knowledge, skills, and attitudes fundamental to holistic care.

The Transition to Practice Seminar

BY JONATHAN F. BORUS, M.D.

The author discusses the lack of organized faculty attempts to facilitate psychiatric residents' transition to professional practice. Interviewed residents suggested that faculty discontinue their "benign neglect" of the transition and provide information and discussion regarding the realities of different types of practice. He describes the six-session seminar he developed at Massachusetts General Hospital, which focuses on the process of transition from residency to practice, emphasizes the role of faculty as decision facilitators, and explores the costs and benefits of different types of psychiatric practice.

THE TRANSITION from residency to practice is an important and stressful period of professional development that annually affects one-third of all psychiatric residents. In the past, obligatory military service at the end of residency provided most psychiatristis with a two-year moratorium during which they could consolidate their professional identities—while practicing semi-autonomously in a sheltered institutional environment—and leisurely explore postmilitary practice opportunities. The discontinuation of the physician's draft in the early 1970s ended this sanctioned hiatus between training and practice and has pushed decision making about practice into the final year of residency training, making it a legitimate concern of senior residents and training program faculty.

Despite the fact that this predictable transition period comes at the culmination of the prolonged formal medical educational process and helps determine the ways in which residents will use their extensive training, there has been surprisingly little attention paid to it in the professional literature. I conducted a five-year interview study of 61 senior residents graduating from the residency training program of the Massachusetts General Hospital Department of Psychiatry and Harvard Medical School and describe elsewhere[1] the issues facing residents in this stressful a[illegible] tressing transition period and some o[illegible] and affective ways in which residents c[illegible] transition.

THE NEED FOR FACULTY INTERVEN[illegible]

During the transition to practice resid[illegible] fine, weigh, and assign relative priorities [illegible] flicting professional aspirations, pers[illegible] ily expectations, and practice opportu[illegible] a satisfactory practice plan. Recent [illegible] atric Association meeting panels [illegible] cussions at training directors' mee[illegible] anaugh's article (2) on postresidency c[illegible] focused on the need for faculty to fi[illegible] senior residents in this decision-ma[illegible] though specific faculty interventio[illegible] groups, regular meetings with trainin[illegible] courses in autognosis) to facilitate t[illegible] into psychiatric residency are freque[illegible] the literature revealed only a single d[illegible] formal faculty program to facilitate [illegible] tion from training to psychiatric prac[illegible] per, Allen (3) described a seminar at [illegible] which he discussed with a group of se[illegible] practical and ethical issues of enterin[illegible] therapy practice.

There have been many hypotheses ab[illegible] have not been more organized facult[illegible] cilitate residents' transition to practice [illegible] that the annual loss of highly cathected [illegible] progeny is such a painful event for a[illegible] deny or minimize the importance of this [illegible] the residents. Others suggest that sinc[illegible] residents are clearly competent adult [illegible] any attempt by faculty to intervene in [illegible] making would be inappropriately intrusi[illegible] tal. At the opposite end of the spectrum [illegible] tion that because residents become pract[illegible] end of training, they pose a competitive t[illegible] ty members with whom they will be co[illegible] variety of limited practice resources (e.[illegible] ferrals, research monies, and academic a[illegible] al positions) and that in areas that a[illegible] with psychiatrists faculty are not engag[illegible] more recently trained competition. Wha[illegible] sons, I believe it is clearly within the r[illegible] make formal efforts to facilitate (curious [illegible] and "facilitate" have the common Lati[illegible]

easy) the growthful transition of their residents from trainees to psychiatric practitioners.

In this paper I will delineate some of the faculty interventions suggested by Massachusetts General senior residents in the interview study I conducted to facilitate their transition to practice and discuss some of the attempts of our faculty to meet transition needs. I will specifically describe a major faculty intervention, the "Transition to Practice Seminar," which has been part of the training program's core curriculum for all third-year residents over the last four years.

FACULTY FACILITATION OF THE TRANSITION TO PRACTICE

The residents I interviewed described three types of faculty interventions that they felt could be helpful to their transition decision making. These were that faculty should 1) legitimate and openly discuss the transition as a stressful part of residency training and an important part of professional development; 2) encourage residents to consult specific faculty members as decision facilitators to help each resident define his or her professional strengths, skills, and identity, and to discuss the rewards and costs of different types of psychiatric practice; and 3) provide information to aid the exploration of specific practice opportunities.

The most basic intervention suggested was for faculty to discontinue the attitude of "benign neglect" toward the transition to practice and legitimate open discussion of this transition as a stressful, important part of professional development that occurs expectedly in the final year of residency training. The residents felt that faculty should focus on the end of residency as an important part of the total training experience in a manner similar to the emphasis psychiatrists put on the termination of other relationships. Faculty should familiarize residents with the process of this termination and the decision-making tasks of the transition to practice, the normality of stress during this period, and methods used by previous residents to actively cope with this transition. They should also state formally their receptivity to and availability for discussion of transition decisions in order to decrease residents' apprehension that approaching staff for help with transition issues will stigmatize them or be interpreted as individual immaturity or psychopathology.

The second suggested intervention was for faculty to encourage residents to use individual staff members as decision facilitators during the transition. This could begin by the training director reviewing with each resident early in the final year of training the faculty's evaluation of his or her strengths and weaknesses and the practice areas that interest him or her. The training director could then suggest faculty members with specific expertise and contacts in the resident's areas of interest with whom he or she could explore strategies for practice-seeking early in the year and discuss the pros and cons of different types of practice opportunities or offers as they arise.

Because psychiatric residents often do not get the opportunity to observe closely how their supervisors and other role models actually practice, they could also benefit from candid discussion with practitioners in their area of interest of the day-to-day costs and benefits of that type of practice. At a later point in the transition period such decision facilitators could also be helpful in discussing some of the practical but often taboo issues concerned with entering practice, for example, prevailing fee schedules, office and billing procedures, debt collection, and interaction with third-party payers for those interested in private practice; and the intricacies of academic politics, requirements for academic rank, and grantsmanship hints for those interested in academic-research practice. These important practical realities are frequently left up to each new practitioner to rediscover, often through repetition of avoidable mistakes.

The final type of helpful faculty intervention suggested was the provision of information about and linkages to specific practice opportunities. A file of job opportunities could be maintained and a listing of faculty members with contacts in various subspecialty practice areas throughout the country could be compiled to provide residents with information on whom to check with concerning opportunities in a specific area or institution. This is especially important for those residents interested in academic-research careers because the academic buddy system often influences both the dissemination of information about junior faculty positions and who eventually gets hired.

THE TRANSITION TO PRACTICE SEMINAR

From these suggestions I developed a six-session weekly seminar at Massachusetts General Hospital for all third-year residents, which has been part of the core curriculum since 1974. Although officially titled "The Transition to Practice Seminar," it has become known among the residents as "Reality Rounds" because of its focus on many of the reality issues and problems of choosing and entering a psychiatric practice. The goals of this brief seminar, which is given each September, are to focus the attention of senior residents on the decision-making tasks that lie ahead of them and provide them with opportunities to learn about the realities of a variety of types of psychiatric practice.

The seminar is divided into three segments. The first session is devoted to a presentation from my research data about some of the issues, stresses, and options commonly involved in the transition to practice. The types of personal, professional, family, and practice opportunity variables that must be considered and assigned priorities are described as well as the process of exploring the costs and benefits of practice opportunities and negotiating for the practice rewards necessary to make the cost-benefit ratio a satisfactory one. In ad-

dition, some of the common affective reactions (increased anxiety, depression) experienced by residents in response to the stresses of the transition to practice are delineated to help the residents anticipate them as normal and ubiquitous. Lastly, I emphasize the availability and potential usefulness of the faculty as decision facilitators in the coming months.

The next four sessions are devoted to the careful exploration of different types of psychiatric practice. In successive weeks active practitioners of general psychiatry, academic-research psychiatry, administrative-teaching psychiatry, and private office psychotherapy make themselves available for open-ended dialogues with the residents about the realities of their practices. Two practitioners participate in each session, one senior and one relatively recent to practice, so that the residents can explore both the long-term potential and the current entry opportunities of that practice type.

After brief introductory statements by the two practitioners, the major part of each seminar is devoted to a no-holds-barred discussion in which the residents are encouraged to ask the practitioners any questions that will give them greater insight into the professional and personal sides of the life associated with that type of practice. The residents frequently probe the practitioners' personal reasons for choosing that particular type of practice; how they got started and what their advice is for starting such a practice today; what their perceptions of the most important rewards of their type of practice are (i.e., what level of income, academic status, professional stimulation, time for family and personal pursuits, and other rewards their practice provides) and what its costs, complications, and frustrations are; and over the years what their major likes and dislikes in their practices have been and what trade-offs or compromises their type of practice has required for success and satisfaction.

These sessions have often given the residents their first feel for the realities of practice, which they will soon face, such as the politics and hierarchy of their own and other academic institutions, the business ends of private practice and assessments of the availability of patient referrals in Boston and other locations, methods for seeking research support, and techniques for dealing with the bureaucracy of public or academic institutions or delivery systems. The faculty practitioners who have participated in these sessions over the years have been exceedingly courageous in sharing important parts of their personal and professional lives with the residents; this openness has demonstrated the true availability of faculty to discuss such issues with residents as they grapple in the coming months with decisions about practice.

The final session has been devoted in recent years to a "New Practitioners' Panel" in which residents who have graduated from the training program and entered their own practices in the last few months discuss their very recent transitions to practice. These neophyte practitioners, only one year ahead of the residents in the seminar, have been able to bring [illegible] sions and immediacy of the decision-ma[illegible] ing the senior residents and to share [illegible] recently planned and experienced the [illegible] their new practices. Resident questio[illegible] are more focused on "What's it like?" [illegible] go about it?" "How does it feel?" [illegible] Massachusetts General's training [illegible] market?" issues that the current res[illegible] fortable asking their colleagues from t[illegible] who have gone through the transit[illegible] training under similar market circum[illegible]

RESPONSE TO THE SEMINAR

In general, the Transition to Prac[illegible] been very well received by the resi[illegible] resident reaction during the seminar i[illegible] creased anxiety as the seminar bre[illegible] dents' denial and confronts them wi[illegible] the coming months they will have to [illegible] decisions that will have many ramif[illegible] lives. The seminar couples raising o[illegible] concurrent provision of information [illegible] help the residents begin an active exp[illegible] internal professional self-definition a[illegible] tiations for practice opportunities.

When interviewed individually nea[illegible] residencies six to nine months later (a[illegible] tinuing research project), the resident [illegible] positive about the seminar, and man[illegible] been an important stimulus to their a[illegible] in the decision-making process. Man[illegible] the seminar's description of the tra[illegible] helpful in their mapping a strategy fo[illegible] tice opportunities, anticipating the st[illegible] sion-making period, and understandi[illegible] tions to it. Several said that the sem[illegible] useful insights into the professional a[illegible] ties of the various types of psychiatric[illegible] some found these insights useful in [illegible] practice area in or out for intensive [illegible] exploration. Several residents cited the [illegible] seminar faculty as a convincing dem[illegible] faculty's desire to help in their trans[illegible] and some said that the practitioners [illegible] tions of their continued developmen[illegible] skills after residency and the continu[illegible] nities for shifts in practice decrease[illegible] these residents felt to make "final" [illegible] helped them put the transition to prac[illegible] spective of an important one of many [illegible] course of their professional develop[illegible]

CONCLUSIONS

In many residency programs, the t[illegible] training to practice is ignored, and resi[illegible]

information about or help with the important issues raised by this stressful stage in professional development must attempt individually to find help on their own. This benign neglect increases the isolation and apprehension that residents feel in making decisions about practice, reinforces normal denial that significant life changes will occur at the end of training, and may delay active coping efforts in this predictably stressful professional transition. In this report I have described some of the ways in which training program faculty can facilitate the transition of their residents to practice and a specific core curriculum seminar used over the last four years by the Massachusetts General Hospital Department of Psychiatry to meet some of these resident needs. We have found this type of intervention relatively easy and inexpensive to provide, and our senior residents have found it to be of great benefit. Although specific aspects of the transition to practice may be different in other settings, many of the issues raised are faced by most psychiatric graduates, and the faculty interventions described above can be replicated by other training programs to achieve similar beneficial effects.

Supervision and the Professional Development of the Psychiatric Resident

BY JOHN J. DRUCKER, M.D., DAVID B. KLASS, M.D, AND MICHAEL STRIZICH

The authors used a questionnaire survey to study the way psychiatric residents experience their psychotherapy supervisors at two points in their training. Results show that second-year residents were more critical in their evaluations of supervisors than first- or third-year residents and that there appeared to be a characteristic progression in the experience of residents from year to year. The authors believe that the resident's experience of supervision reflects a developmental process, which others have described and viewed as important in the formation of identity as a psychiatrist.

Dr. Drucker is Assistant Professor, Departments of Medicine and Psychiatry, Minnesota Medical School, and Staff Physician, Section of Psychological Medicine, Minneapolis Veterans Administration Medical Center, 54th St. and 48th Ave. South, Minneapolis, Minn. 55417. At the time this work was done he was a resident in psychiatry at the University of Chicago Hospitals and Clinics, Chicago, Ill. Dr. Klass is Lecturer in Psychiatry, Department of Psychiatry, University of Chicago, and Mr. Strizich is Consultant to the State of Illinois Department of Mental Health and Developmental Disabilities, Chicago, Ill.

The authors wish to thank William Offenkrantz, M.D., for his rating of the supervisors.

A NUMBER OF REPORTS have focused on psychotherapy supervision as an important part of the psychiatric resident's training. Our own observations of residents' difficulties and satisfactions with supervisors suggested a relationship between the residents' experience in supervision and the process of their professional development. Our initial approach was influenced by the classic work of Holt and Luborsky (1), who emphasized the need for clinical research in psychiatric education to combine with the strength of statistical techniques in achieving more powerful findings. The existing literature discusses problems residents experience in supervision (2–6) and their professional identity development (7–8), but we could find no studies that used quantitative methods to measure changes in residents' attitudes toward supervisors in an attempt to clarify the relationship between the supervisory experience and professional development. Sharaf and Levinson (9, 10) developed a scale based on attitudes of senior faculty and used it to reflect changes in residents' therapeutic ideology over the course of the residency. However, they did not quantitatively evaluate the process of supervision as we report here. Most of the supervision studies reported are based on observations that are unsystematic. We felt

0002-953X/78/0012-1516$0.45 © 1978 American Psychiatric Association

that an attempt to quantify changes in attitudes toward the supervisory experience would be a useful contribution to research in the area as well as an aid in formulating a theory of professional development.

This study takes for granted that residents' responses to questionnaires concerning supervision not only relate to their outside world (i.e., their supervisors) but also inform us about the internal structure of the perceiver (the resident).

METHOD

During the second year of his residency, one of us (J.J.D.) actively participated in open criticism of the psychotherapy supervision program. In an attempt to collect systematic observations and complaints about all supervisors, this author developed a questionnaire for resident use in evaluating psychotherapy supervisors. The original purpose of the evaluation was to document for the residency director what residents felt were supervisors' deficiencies. Items on the questionnaire were generated by discussions with residents and faculty and from texts of psychotherapy and resident supervision (5, 6, 11). Faculty were also invited to offer suggestions and criticisms of the questionnaire. The final form was constructed by one of us (J.J.D.) with the general consensus of his resident colleagues.[1]

The questionnaire consisted of a section of 16 items in which residents rated specific aspects of their psychotherapy supervisors. Items covered the supervisor's attendance, interest in supervision, empathy for patients, ability to elucidate psychodynamics, ability to use alternate conceptual models of therapy, encouragement of the resident's capacity for self-observation, and other areas.

Questionnaires were given to all residents. A separate questionnaire was completed for each of the resident's 2 or 3 psychotherapy supervisors assigned for a 12-month period. Each item was rated on a scale of 1–5 (1=poor, 5=excellent). In addition, residents gave a "global rating" indicating the overall helpfulness of the supervisor. Written comments about each supervisor were solicited at the end of the questionnaire.

The results of the initial survey surprised us in demonstrating how inept all of the second-year supervisors seemed to be. At this point, we began to suspect that the low ratings of supervisors assigned to the second-year residents pointed to an attribute of second-year residents. Of course, it was possible that the low ratings simply meant that all of the poor supervisors were in fact assigned to the second year, or that this particular group of second-year residents rated things unfavorably even before entering psychiatric training. We hypothesized, however, that the resident's developing and somewhat conflicted professional identity was a factor in how he or she rated the supervisors. If so, we could use the supervision questionnaire [illegible] titude changes in residents.

Without revealing to the residents the [illegible] initial study, we repeated the survey [illegible] This gave us an opportunity to replicate [illegible] results as part of a longitudinal study and [illegible] portunities to test whether residency [illegible] ing. Two classes of residents were followed [illegible] nally: one group consisted of those in their [illegible] ond year and the other consisted of those [illegible] to third year. We wondered whether [illegible] pervisors would again be rated poorly by [illegible] of second-year residents.

We then compared residents' ratings [illegible] while correcting for the possibility of [illegible] tion of supervisors across years. We [illegible] faculty psychiatrist (the former resident [illegible] who knew each supervisor's professional [illegible] experience well, to independently rate [illegible] according to his own global assessment [illegible] sor's skills. Using this independent rating [illegible] ed residents' global ratings in each year [illegible] squares regression. We used the resulting [illegible] equation to represent each resident's [illegible] the analysis of variance. The above procedure [illegible] control for the fact that supervisors were [illegible] assigned on a random basis to residents [illegible] three years, leading to a possible bias [illegible] good and bad supervisors. The former resident [illegible] tor gave only a global rating because it [illegible] to have him rate each supervisor on each [illegible] vidual items.

Data were analyzed by analysis of [illegible] cover possible differences in ratings [illegible] years. A multiple regression analysis [illegible] sample of residents studied longitudinally [illegible] with the residents' global ratings as the [illegible] iable and the 16 individual items as the [illegible] variables. This regression analysis, designed [illegible] the relative contribution of each of the 16 [illegible] variables to the global rating, showed that [illegible] were highly correlated with the global rating [illegible] no particular variable stood out in importance [illegible] therefore added all of the individual items [illegible] obtain a global rating with a larger base [illegible] nal global rating, which was only a single [illegible] on a 5-point scale. This total score was [illegible] analysis of covariance as explained above [illegible] al score, i.e., with the residual scores [illegible]

RESULTS

The response rate was 92% on the 1975 [illegible] 26 residents) and 100% in 1976 (23 of [illegible] Thirty-three different supervisors were [illegible] year, and about two-thirds of these were [illegible] than 1 resident each year. In the data [illegible] questionnaire was considered separately [illegible] each of the two surveys were 56 and 53. [illegible]

[1]Copies of the questionnaire are available from Dr. Drucker on request.

***Significantly different from first- and third-year groups ($p<.04$, $F=4.46$, $df=1,50$).
†Significantly different from first- and third-year groups ($p<.03$, $F=5.33$, $df=1,50$).

corresponding to the number of questionnaires completed each year.

On each of the two sampling occasions, the relationships of the residual global ratings across resident years were identical. Residual global rating refers to the global rating after correction for possible biased distribution of supervisors according to the senior psychiatrist's rating. The second-year residents had significantly lower residual global ratings compared with the first- and third-year groups ($p<.004$ in 1975 and $p<.03$ in 1976) (see table 1). Negative numbers indicate that second-year residents' ratings clustered in a direction opposite those of their first- and third-year colleagues in the analysis of variance. Results were the same for the total scores (see table 1).

A striking pattern followed by the raw scores on all 16 items as well as the global ratings was a V-shaped one of high ratings in years one and three and low ratings in year two (see figure 1). However, it was only the residual global ratings that showed any significant differences across resident years. None of the 16 individual items showed significant differences.

The two groups that were followed longitudinally were compared against themselves for the two time periods covering a 15-month interval. The first-year residents in 1975 who became second-year residents in 1976 moved in the direction of lower ratings in the second year; this change just missed statistical significance ($p<.06$). The second-year residents in 1975 who became third-year residents in 1976 gave significantly higher ratings ($p<.0003$) in their third year compared with their second year. These changes show that the original low ratings by second-year residents were not due to their being a group of consistently low raters.

COMMENT

Results of the multiple regression analysis demonstrated the high internal consistency of the rating scale we developed. The 16 items provided a framework on the 1–5 scale indicating to residents what factors should be taken into account in making their global ratings. The global ratings were thus not haphazard guesses but were based on the preceding variables, as the high correlation between all items and the global ratings shows. When we saw the differences across years in the residual global ratings, we expected to see differences in at least some of the 16 independent variables that might explain these differences. However, there were none. No item was independent of the others. Perhaps if the independent variables were cor-

rected by having the senior psychiatrist rate them and then testing them in an analysis similar to the global ratings, differences might have emerged.

Although the profiles of the independent variables did not vary, an interesting finding was the depression of the whole scale in the second year compared with the first and third years. This paralleled the low residual global ratings in the second year. Our data clearly document that residents' experiences of psychotherapy supervision follow the "second year slump" discussed by Sadock and Kaplan (12). They described this period as characterized by "vague dissatisfaction leading to persistent complaints and formal protests against the institutional structure. Whereas the first year of the residency is characterized by eagerness, enthusiasm, and a glowing desire to learn, the beginning of the second year is often followed by discontent, dissatisfaction, and negativism." This phenomenon was described in 1959 by Holt (13) in a paper reflecting on the less obvious effects of psychiatric training, unsystematically observed in the process of carrying out a long-term research project at the Menninger School of Psychiatry.

The only study we found quantifying this "slump" is that of Pasnau and Bayley (14), who found MMPI depression scales elevated in residents at the end of their first year compared with their entering scores. The literature indicates that residents in almost every program complain about not getting enough good psychotherapy supervision (15); our study points out that these complaints, at least in some degree, are part of the slump. Further, although our measurements are different from the standardized MMPI profiles of Pasnau and Bayley's report, our findings go beyond their work in showing that residents seem to snap out of the slump by the third year. We have no data on whether or not our residents were in personal psychotherapy before, during, or after our surveys. An increasing number of residents enter treatment as the residency progresses. It would be interesting to know whether residents come out of the slump with or without therapy.

How do we explain the existence of the second-year slump? We agree with others (7, 8, 13, 16) that it may represent part of the process of identity development as a psychiatrist. Psychiatric training imposes major stresses on the resident's developing identity (17), and a "regression in the service of residency education" occurs as an adaptive step in the process. Shershow and Savodnik (18) used this phrase to describe certain behaviors of first-year residents on an inpatient unit. Although we believe this process extends [illegible] second year of training, we agree with [illegible] Savodnik that with appropriate super[illegible] vention these regressive behaviors can[illegible] dents' further development as psychiatr[illegible] suggest that this development continues [illegible] year. Our belief that the resident's g[illegible] tion with the supervisor is an impor[illegible] process is supported by Sharaf and Le[illegible] (10) that residents' therapeutic ideolog[illegible] similar to those of their experienced [illegible] the third year of training.

Training Psychiatrists for Working with Blacks in Basic Residency Programs

BY WALTER H. BRADSHAW, JR., M.D.

The author summarizes recommendations on how specific training for working with black and other minority patients can be integrated into the existing relatively traditional residency programs. He also discusses psychotherapeutic issues and problems encountered in biracial and/or transcultural therapy that must be resolved if the training is to succeed.

RESIDENCY TRAINING PROGRAMS today are faced with a variety of competing pressures. There is strong public and government demand to train psychiatrists who will provide services in diverse locations to poor and minority populations (1). At the same time, training programs wish to maintain quality education and avoid role diffusion. Despite the fact that these pressures have been with us for some years, there is a notable lack of specific structure and content regarding the treatment of blacks and other minorities within most residency programs. Thus, psychiatry is called on to treat greater numbers of black people, but psychiatrists are lacking in critical knowledge of black people, the systems that impinge on them, and pertinent growth and development data. Even more serious is the lack of an organized approach to the understanding of the psychodynamics of racial relationships in the United States, factors that are bound to have a profound effect on treatment of blacks within the framework of existing general psychiatry training programs.

PROGRAM STRUCTURE

Orientation to Blacks

The American Psychiatric Association Task Force on the Delivery of Psychiatric Services to Poverty Areas[1] noted that community psychiatric training is generally started late in the residency, after primary attitudes and values regarding psychiatry have been formed. In addition, there is poor integration of knowledge of the dynamic perspective and knowledge of the broader systems relating to primary and secondary prevention that have impact on patients.

In programs that provide services for blacks, from the beginning there should be continuing contact with the agencies and social structures of the community. This contact should involve on-spot visitation. Didactic offerings should include history and ethnic culture, growth and development data, family structure and dynamics, group and community characteristics, sociological literature, and selected readings on "growing up black in America."

Furthermore, literature to dispel myths about blacks should be presented. Briefly stated, here are the main myths: 1) Africans arriving in the United States as slaves were only "primitive stock"; they had no culture or civilization of their own (2). 2) The black family is a "tangle of pathology" (3), as opposed to the white nuclear family. 3) A matriarchal structure is universal in black families. (Hill [4] indicated that the most common authority patterns in lower-class intact black families are more egalitarian than matriarchal.) 4) The black family is in total disarray because of slavery. (Guttman's study of the black family [5] casts serious doubt on this widespread assumption and suggests that family stability has broken down more recently under the impact of urbanization and racism since the 1920s.) 5) Psychopathology is the inevitable consequence of one-parent families; strengths cannot emanate from such families. 6) The black man is totally inferior sexually or, conversely, he is a "super-stud." 7) Blacks rarely develop severe depressions or commit suicide. (Depression is a widespread phenomenon among blacks, and there is an extremely high rate of suicide among young urban blacks [6, 7].)

Also included in this orientation should be group experiences providing the opportunity for residents to role-play minority patients and nonpatients.

Presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2-6, 1977.

Dr. Bradshaw is Assistant Clinical Professor of Psychiatry, Howard University College of Medicine, Washington, D.C., where he was Director of Residency Training in Psychiatry at the time this paper was written. Address reprint requests to him at 3000 Connecticut Ave., N.W., Washington, D.C. 20008.

The author would like to thank Drs. Bruce Ballard, Charles Pinderhughes, Robert Sharpley, Jeanne Spurlock, Timothy Summers, Gertrude Ticho, and Charles Wilkinson for their helpful suggestions on this paper.

Clinical Services

Inpatient and outpatient rotations. Part of the resident's inpatient experience should be conducted in a hospital setting separate from the main training site (i.e., separate from the university hospital). The resident should have the opportunity to diagnose and treat black patients, including those suffering from drug abuse, alcoholism, and severe personality disorders. Part of the outpatient experience should be conducted in a community mental health setting serving a black lower-class population. Diagnostic assessments and work in all forms of psychotherapy should be done on an ongoing basis. It is essential that these experiences be closely supervised by faculty who are sensitive to the minority experience (be they minority members or not). Academically their capacity must be of the highest level because they must be able to dissect the issues most relevant to successful diagnostic assessment and the psychotherapeutic process. Their skills have to include the capacity to evaluate cultural adaptation and identification versus pathology, a finely tuned knowledge of ego functions, the capacity to differentiate the role of reality as reality and as defense, techniques for the fostering of the therapeutic alliance, and sensitivity in the detection of and assistance with working through special countertransferences to minority individuals. It should be obvious that minority faculty would be invaluable for this teaching.

The chronic patient. A disproportionate number of chronic patients are minorities or poor. Their care must be elevated from neglect and being regarded as an unpleasant chore to the status of a legitimate field of training and research. This could be done by providing residents a controlled and supervised experience in constructing, running, assessing, and modifying a small system of mental health care delivery. This should begin early in the residency, preferably as a research project. For example, several sets of two or three residents might construct alternative systems of aftercare delivery using matched groups of patients.

Community consultation. Although it has already been suggested as an important component of approved residency programs, community consultation should be mandated. Assuming adequate supervision, didactic exposure, and seminar discussion, I would suggest a part-time consultation rotation in community agencies serving a lower-class black population.

The residency training director. Implementing such recommendations represents a major extra burden on the training director (8). This person must find and negotiate arrangements with new institutions and field placements, fleshing out the curriculum in the process. Furthermore, strenuous efforts will have to be made to recruit supervisors, many of whom may be uncomfortable with the broader frames of reference and confrontation with their own latent racism. Finally, the director will have to contend with the increase of resident anxiety and identity diffusion inherent in the expansion of their roles, settings, and perspectives.

THE ESSENTIAL EDUCATIONAL EXP

Seminars in psychotherapy conducte the training program should include, a vals (e.g., every three weeks), a con supervisors from both the university a nity facilities join with the trainees to chotherapeutic experience in the diff tings. Among the many possible top ferences and similarities in the patien in the psychotherapeutic technique self-perceptions of trainees in each broader issues of the structure of the and their efficacy in each setting.

One sine qua non of training psych is the development of a complete dia pist. The psychiatrist must have the an accurate diagnosis and to prescrib kind of therapy in any setting. In w patients there are many extra dimen to make this education satisfactory. above to ignorance regarding histo culture, living conditions, and so on portant are the psychodynamics that intertwined with race in every Amer white.

The dynamics of racism and racist psychotherapeutic effectiveness can be all the developmental layers of the Many have contributed to our unde phenomenon (9–14). Pinderhughes (15 have provided the most recent summa a person strives to protect himself ag anxieties precipitated by unacceptab each of his developmental stages by a tal mechanisms. The greater the dif the therapist and the patient, the mor pist would be to ward off his or her o variety of unconscious distancing an neuvers. It is not farfetched to say th goats has been protective of the a white American throughout our co e.g., the initial American attitudes ward the immigrant Chinese, Jews, a outrageous treatment of Native Americ tient's side, Pinderhughes (15) poin group-related paranoia shared by a n it is reinforced by the majority soci intensify the difficulty of psychothera signed to free the person from the crippling of the internalized conflict.

Davis and Coleman (17) stated th whelming problems of lower-class ghetto to the internalization of a hostile objec culty in establishing a stable ego ideal. uncertainty of continuity ("average ex ronment") can lead to adaptations tha the here and now, precocious self-suf constriction of intellectual freedom and c multiple disruptions of secondary auto

the same line, Spurlock (18) mentioned the constriction of hope, fantasy, and cognition that leads to intellectual underachievement and chronic depression. On the other hand, these authors have strongly pointed out the tendency of white psychiatrists to overgeneralize middle-class standards of development as the norm, thus overlooking the adaptive capacities of the ghetto-raised child. Notwithstanding multiple mothering via extended families, many of our ghetto residents manage to grow up without mental disorder. These authors also pointed out that psychiatrists neglect the synthetic ego function of the ghetto resident that allows for maximum adaptation to the reality of existing in a world in which expectations are frequently frustrated. Further, these authors stated that in looking at ghetto families, psychiatrists have paid no attention to the strengths within such families. With these biases, there is an inevitable tendency to prematurely label or mislabel as psychopathological some of the phenomena manifested by black patients.

The extremity of distortion that can result from such tunnel vision regarding the black patient has been pointed out by Thomas and Sillen (19) in their comment on Kardiner and Ovesey's *The Mark of Oppression* (20). In the latter work a major hypothesis is that blacks have practically no possible basis for healthy self-esteem and almost every possible incentive for self-hatred, a dogmatic overgeneralization of an entire people. We see a similar attitude in the tendency to glibly overextend psychoanalytic concepts to explain an entire people, e.g., the idea that slavery reduced all blacks to an infantile-oral-dependent level. Likewise, it is seen in the tendency to perceive differences from the white culture as representative of the "deficit model," according to which variations in the use of language, syntax, attitudes toward time, and other aspects of the dominant culture are assumed to be psychopathological, even among children. This latter idea has been effectively refuted by many, including Coles (21), who noted the resilience and ingenuity of the black schoolchildren who first entered desegregated schools in both the South and the North.

More subtle preconceptions can creep into the use of shorthand terminology, such as "culturally disadvantaged," "slow learner," and other phrases, however well-intentioned these were in their original descriptive origins (22). This is illustrated by a 1968 study (23) in which one group of students was represented to their teachers as late spurters while another group was not. Both groups were in fact matched. However, the children who had been identified as late spurters did so academically, while those who had not did not. Like the teachers in this study, mental health professionals can easily have entire stereotyped pictures called to mind with the use of a single phrase. Furthermore, to many black children the phrases "culturally disadvantaged" and "slow learner" have become the equivalents of the epithet "nigger" and represent just another instance of the micro-aggressions beating daily on their self-esteem.

With this background in mind, there are specific ways in which countertransference and technique errors impinge on the evaluation and treatment of black patients. One such error is that premature closure is instituted on patient evaluation or treatment with the rationalization that the patient is unsuitable for psychotherapy because the patient has difficulties with impulse control, verbalization, ego deficits, and so on. A variant of the same theme is occasionally heard from some black mental health professionals, who argue that dynamic psychotherapy is not suitable for black patients because it is too cold and intellectualized, that the average black patient's needs are more immediate, and that it is not relevant to the patient's struggles in the world. This strikes me as being partially tinged by the unconscious adoption of some of the racist myths about black people that are prevalent in our society. These remarks have certain implications, e.g., that black patients do not have the ego strength to tolerate some forms of therapy, that they do not have the ego capacity to form a therapeutic alliance even when they receive an appropriate preparatory education by therapists about the way some forms of therapy are conducted, that they do not have the capacity to use insight in relation to their own personal dynamics, that they must be invariably and strenuously infantilized, and that they do not have the capacity to use therapeutic methods that are specifically designed to offer the maximum opportunity for ego autonomy and freedom from neurotic conflicts.

Ticho (24) described a case in which she was psychoanalyzing a patient in a foreign country when she experienced a temporary breakdown of empathy and a reaction of distrust toward the patient. She recognized this reaction as projection. The impairment of her skills was reinforced by the fact that not only was she deprived of the internal identification with the patient (a foreigner) but also by the fact that she was deprived of the support of her own familiar culture.

Another error made in therapy with black patients is that everything the patient says is interpreted in glib reductionist constructs involving racial stereotypes or psychoanalytic jargon. The opposite problem can also occur: nothing the patient says is considered in relation to race—a kind of global denial or avoidance by the therapist—or all references to race are immediately defined as defensive, without any regard for the internal and external realities of the patient's life as a black person in the United States.

A potpourri of overidentifications, overcompensations, condescension, and flight, all linked together by countertransference involving warded-off aggression and/or compensatory mechanisms against feelings of inferiority and badness, can also occur. One of the more typical patterns seen, particularly in a beginning therapist confronted with feelings of increasing impotence or narcissistic injury, is the tendency to abandon psychotherapy completely and fling himself or herself into a group situation that is going to restore all mental health by changing the community. The resident can

thus become part of a hopeful situation involving an infallible force that would change the world. This reaction is also linked to the therapist's having difficulty with aggression, which is warded off by joining with the patient in an assault on the projected evil outside.

Other therapists, although they do not flee headlong from psychotherapy, may keep the patient in treatment in a condescending oversolicitous relationship in which the patient is never confronted on critical issues either within the patient's external world or the transference. In a situation in which a black patient is involved in significant amounts of destructive acting out, the white therapist may receive the added bonus via identification of satisfying his or her own aggressive impulses vicariously from a relatively protected and self-righteous position.

Schacter and Butts (25) and Grier and Cobbs (26) have described how references to race, the use of subcultural language differences, and the gross acting out of racial stereotypes can be used primarily in the service of resistance in therapy—with both therapist and patient engaged in mutual avoidance. Often, because of the projected fear of the blacks' retaliatory aggression, the therapist rationalizes his or her overemphasis on culture by saying that to do otherwise would be "trying to make the patient white."

Poussaint and Ladner (27-29) have gone into some detail regarding a particular type of masochistic overcompensation that has relevance to psychotherapeutic relationships. In this variant a white person compensating for feelings of inferiority and badness approaches the relationship with rescue fantasies involving unconscious feelings of superiority. When confronted by a black person's perception of the racist attitudes inherent in that position, the white person then either flees or places himself in the position of being abused masochistically.

It is clear that the task of the supervisor is made more complex by the issues raised here. Jones and associates (30) indicated that in their experience in residency training they found similar patterns in their supervisors' treatment of them and in the supervisors' advice regarding their black patients. Basically, if supervisors are not sensitive to these issues and have not confronted their own unconscious racism, it is unlikely they can help residents to do so. Once again, one can see the importance of recruiting minority faculty.

GENERAL PRINCIPLES

There are several fundamental and deceptively obvious guides for the therapist. The first is that therapists must engage in continuous introspection and self-analysis. Even more rigorous attention must be paid when there is a transcultural or biracial situation because the therapist is in greater danger of regressing and projecting when the patient or external environment seems significantly unfamiliar.

Therapists must make a serious effort to learn as much as possible about the culture of [illegible] that they have some comprehension [illegible] sents "normality" and ego-syntonic [illegible] patient. This will help to avoid the assumption that [illegible] understand the meaning of everything [illegible] Therapists must be more active in asking [illegible] what the patient means by a particular [illegible] or anecdote.

There must be some acknowledgment [illegible] directly or indirectly, of the therapist's [illegible] the realities of the external racist environment [illegible] pressures to which the patient is subjected [illegible] patient does not experience the reality [illegible] therapeutic alliance may be impossible [illegible] although the therapist must remain aware [illegible] tial dangers of infantilizing the patient [illegible] times when it is necessary to help the patient [illegible] the realities of external existence before [illegible] ous with the internal conflicts.

Therapists must recognize and become [illegible] with their own and their patients' ages [illegible] varying and different perspectives. For [illegible] black power movement had a significant [illegible] as a phase of self-assertiveness that enhanced [illegible] tal health of black people in this country [illegible] with black patients, therapists must [illegible] adaptive value of autonomous constructive [illegible] tive action, thought, and feeling and not [illegible] by it. However, on the other side of the [illegible] must be prepared to deal with the noradaptive [illegible] of aggression and neuroses of black patients [illegible] obstacles these place in the path of psychotherapy [illegible] of these have been outlined by Pinderhughes [illegible] nial, paranoid feelings and distrust, silence [illegible] passivity, precipitation of crises, and [illegible] payment of bills, and missed appointments [illegible] phenomena frequently represent indirect [illegible] due to fear of assertiveness in the psychotherapy [illegible] though they may have been adaptive defenses [illegible] and historically (and, as mentioned above, [illegible] by the dominant society in the present) they [illegible] sent maladaptations in the present. Pinderhughes [illegible] vocates quick identification and interpretation [illegible] resistance in order to engage the patient's [illegible] ful attention following any therapeutic [illegible] determine whether distortion has occurred [illegible] jection or misunderstanding via subcultural [illegible]

Within the context of a therapeutic relationship [illegible] which the alliance is secure, not only can [illegible] gin but it can flourish with black patients [illegible] dismissed as "unsuitable." Psychiatric Education and Training of Asian and Asian-American Psychiatrists

BY NORMUND WONG, M.D.

The Asian and Asian-American physician in a standard psychiatric residency is faced with discrimination at several levels, as well as special problems of professional role confusion and personal identity, all of which can create barriers to professional development and productivity. Further, most standard psychiatric residencies do not include teaching or supervision specific to treating Asian patients. The author proposes the establishment of a specialized program, focusing on ethnic minority groups, within a general psychiatric residency; he discusses specific features of such a program. This approach may help to alleviate the problem of inadequate resources for handling the mental health problems of Asian-Americans and underutilization of mental health resources by this group.

WHAT HAPPENS when an American citizen with an Asian background becomes mentally ill, especially when that individual has lived for many years in a racial ghetto? Historically engulfed by hostile and culturally foreign environs, Asian-Americans tend to cluster together for mutual assistance and comfort—to have ready access to customary foodstuffs and to communicate in and perpetuate the native language and cherished customs. All too often Asian-Americans tend to keep mental health problems a family affair. By the time they seek outside help at a mental health facility, personal resources have been depleted, the family unit is exhausted and angry, and intrafamilial strife has become overwhelming. As a result, an appeal for outside help often signifies a rejection of the sick member by the family and community.

At the mental health facility the Asian-American patient is seldom seen by a psychiatrist who understands his or her traditions and mores, even if the psychiatrist also happens to be an Asian-American. Although the psychiatrist may have graduated from [illegible] garded residency he or she probably [illegible] speak the Asian patient's language. Ce[illegible] will be difficult to diagnose and treat [illegible].

A recent survey (1) revealed that of t[illegible] Asian-American psychiatric residents [illegible] Menninger School of Psychiatry, onl[illegible] treated an Asian patient while in trai[illegible] there are several hundred Asians in the [illegible] The same situation exists in large citie[illegible] and West coasts, where the Asian pop[illegible] mense by comparison. It is small [illegible] Asian-American citizens find much [illegible] with our psychiatric service delivery sy[illegible]

Asian-Americans represent a signifi[illegible] of the U.S. population and are a heter[illegible] complex group with diverse religions, [illegible] guages, and histories. For example, acc[illegible] census data, there were 1,439,412 pers[illegible] origin living in the United States: of [illegible] were Chinese, 249,145 were Filipinos, [illegible] were Japanese. Certain racial myths exis[illegible] Americans. They have been stereotyped [illegible] zens who are quiet, self-sufficient, ind[illegible] well adjusted to the American society [illegible] ever, this image is being dispelled by [illegible] studies. Within Asian-American popul[illegible] an increasing incidence of suicide, alco[illegible] nile delinquency, and drug addiction. A [illegible] vestigators feel that psychopathology [illegible] Americans has been underestimated and [illegible] resources for handling their mental he[illegible] are inadequate (6, 7, 12–16).

The necessity to develop meaningful [illegible] mental health care programs for Asian [illegible] obvious and has been recognized by [illegible] 1974, when it made available through [illegible] Psychiatric Association stipends to incr[illegible] ber of minorities in the mental health f[illegible] 1975 the National Advisory Mental H[illegible] Subcommittee on Minority Related Re[illegible] mended that at least 20% of all NIMH f[illegible] for "relevant research areas" be earmar[illegible] ity studies by the end of fiscal year 19[illegible] recognition of this problem, the Presid[illegible] sion on Mental Health in 1977 designate[illegible] study the mental health of Asian-Americ[illegible] ic Islanders.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2-6, 1977.

Dr. Wong is Director, Department of Education and the Menninger School of Psychiatry, the Menninger Foundation, Box 829, Topeka, Kan. 66601. He is also Adjunct Associate Professor of Psychiatry, Temple University School of Medicine, Philadelphia, Pa.

TRAINING AND EDUCATION ISSUES

This paper addresses two specific issues in the training and education of Asian and Asian-American psychiatrists. First, I will discuss the plight of the Asian-American physician in a standard psychiatric residency and second, I will conceptualize a residency program especially aimed at preparing Asian-American and Asian psychiatrists to treat Asian-American populations. The educational principles buttressing such a program might well apply to any psychiatric training program with the explicit goal of treating minority group patients.

Asian-American Trainees in a Standard Psychiatric Residency

Institutional racism is experienced by even the most acculturated Asian-American U.S. medical school graduate. It is beyond the scope of this paper to discuss the plight of the Asian foreign medical graduate; however, suffice it to say that discrimination is present in even more gross and blatant forms.

The American-born Asian trainee is confronted by issues different from those experienced by his white counterpart. Despite his or her credentials, faculty members and patients consciously or unconsciously tend to equate him or her with the foreign medical graduate. He may encounter discrimination even before entering the training program. The Asian-American's name often causes the admissions committee to engage in stereotyped fantasies about his alleged docility, passivity, inscrutability, mysterious Asian upbringing, and lack of adaptability to Western mores. He encounters these same fantasies throughout his residency years from a succession of clinical and teaching staff members. Although he may be a third-generation American he remains highly visible. He does not blend easily into the white population. Consequently, he might become entangled in a self-fulfilling prophecy. The faculty and staff of the program may have assuaged any guilt about discriminatory practices by accepting him for training. However, discrimination may exist on an overt or covert level. As a resident, he might be accepted on the same footing as any of the white trainees; such a move would be very appropriate. However, even then, especially for a second-generation Asian-American, the positive cultural and personal assets that he brings to his training might be lost or devalued in a subtle fashion.

Much has been written about the psychiatric trainee's identity crisis and penchant for role confusion. It is generally acknowledged that a successful resolution often hinges on identification with an admired teacher. The task is more complicated for the American-born Asian trainee, who must not only contend with his professional role confusion but must also resolve the matter of his personal identity. Unlike his white counterpart, he rarely has contact with an American-born Asian psychiatrist after whom he can model himself. In treating patients he may encounter initial relationship and transference problems due to his projected image; these problems usually do not arise among other trainees, and they may not be readily apparent to his supervisors. If a strong tendency exists to stereotype him, the staff may assign him primarily non-dynamically oriented and traditionally less desirable patients, minority patients, or multiproblem patients, and in general offer him a less satisfactory psychotherapy training experience than his peers. He may be steered into research tracks with fewer patient contacts.

Should he seek psychoanalytic training, he is likely to encounter the same, although more intensive, biases that he experienced when applying for residency training. Gross generalizations may abound, excluding individual considerations—for example, "It is not possible for a therapist to analyze an individual of another race because of the divergency of psychological biases." "Asians are so obedient, intellectually defended, and need so much structure that free association and therefore analysis are impossible." Despite these views there are a small number of American-born Asian graduates of psychoanalytic institutes.

Problems of the Graduate

Assuming that the American-born Asian psychiatrist successfully hurdles these difficulties and graduates, he or she may run into a new set of problems. Should he choose to pursue private practice, he must again contend with the image of being a foreign medical graduate whom colleagues and patients may regard as inferior. He must struggle more than most medical graduates if he wishes to establish a private practice in a predominantly white middle-class population. Should he wish to avoid the aggressive and competitive stance required for private practice, he might enter a government system, assume an administrative position, do research, or enter the academic field of psychiatry. In any of these settings he still encounters problems as a consequence of his Asian background.

Sata[1] has pointed out that typically the American-born Asian psychiatrist, as a minority member, is asked to serve on numerous committees that consume inordinate amounts of time and create further barriers to his or her professional development and productivity. Sata also mentioned that the Asian-American may be disliked by white colleagues because his mere presence evokes guilt feelings or defensiveness. In addition, in many institutions there is the unspoken feeling that minority faculty, in order to be found deserving, must work twice as hard. It is probable that even the most successful American-born Asian psychiatrist has experienced some such form of discrimination or difficulty. Aside from the obstacles that he must surmount in order to achieve success, one must take into account the losses both to the Asian-American psychiatrist and the members of his ethnic group as he seeks

[1]Sata LS: Cultural diversity and psychiatric training (unpublished paper, 1973).

to assimilate into a white-oriented psychiatric system. Unless he chooses to practice or teach in a community with a significantly large ethnic population of which he is a member, he is unable to pass on much of the dynamic understanding and successful coping techniques that he may have learned in order to resolve his own struggles and which may be difficult for a therapist of another ethnic background working with Asian-Americans to fully comprehend and empathize with. In addition, American-born Asian psychiatric residents and other professional individuals or students who may be experiencing similar conflicts may not have access to him as a resource.

Finally, if an American-born Asian psychiatrist decides to practice in an Asian-American community, he or she often finds that training is of little practical help. He or she may have retained much knowledge about the religions, mores, and philosophy of his or her ethnic group, but with notable exceptions, nowhere during the standard psychiatric residency was he or she exposed to any teaching or supervision specific to treating Asian patients. Frequently, the American-born Asian psychiatrist has never treated an Asian-American patient during his entire residency. From the few studies available (9, 17), it appears that Asian patients are usually assigned to mental health workers other than psychiatrists and psychologists and are infrequently seen in individual and group therapy. Psychiatric residents are exposed early in their training to notions such as "Asian-American patients generally do not respond well to a psychological approach, are somatically oriented, and are unable to question authority." This induces some American-born Asian psychiatrists to follow an organically oriented approach. If the American-born Asian psychiatrist is trained in a psychodynamically oriented program that places great emphasis and value on the highly verbal patient, he or she may be given little encouragement and time for exploring ways of educating Asian patients to the workings of the psychotherapeutic process. Commonly, such patients are specifically referred to him for a "supportive and drug approach."

Many American-born Asian psychiatrists are poorly informed and ignorant of the culture and language of their own ethnic group. Even if they are motivated to work with Asian-American patients, they may be ill-equipped for the task. For example, of the 84 identified Chinese-speaking psychiatrists in the United States, 9 only speak Cantonese and cannot converse in Mandarin or Toi San. Twenty-one can only speak Mandarin (18). There are only 2 Chinese psychiatrists who reside and work in New York City, where most of New York State's 81,378 Chinese live. One can easily conjure up a Kafkaesque scene in which an emotionally disturbed Chinese patient is finally brought to the office of a Chinese-American psychiatrist, and neither can speak to the other except through a translator. Thus despite the presence of accredited American-trained Asian psychiatrists, Asian-American communities may still lack adequate psychiatric services.

The Need for Specialized Psychiatric Tr... Programs

Just as many trainees select a psychi... that they feel will fulfill their needs to p... in psychoanalysis, research, or comm... try, there should be the opportunity for t... international psychiatric or ethnically s... dency programs. Aside from the progr... versity of Hawaii to train Indonesian ps... establish and practice child psychiatry ... country (19), there are no psychiatric r... grams in the United States that incorpo... ment the cultural, social, and philosophi... that exist among Asian-Americans (20) ... edged among American-born Asian psy... while there is an obvious need for psy... among the Asian-American populatio... psychiatric approach that is taught in ... programs must be modified for most o... (9, 13). Basic research and evaluation ... specific treatment programs with follow... lacking. The following program I prop... suitable for all Asian psychiatrists, not ... can-born Asians.

PROGRAM CURRICULUM

Any program specifically designed to ... psychiatrists must meet the general req... tablished for psychiatric graduate med... However, care must be exercised to a... of courses and clinical experiences in ex... pose hardships on the resident. While ... sible within the standard residency per... Asian-American resident to function a... psychiatrist in his or her ethnic com... probably require additional time and ... the stated goals. Similarly, the trainee in ... try may require extended training. ... should carefully monitor the tra... throughout the program as well as per... studies to justify the value of exten... period beyond the time required for ma... ates.

Formal curriculum must provide ... parative psychopathology (focused on ... ethnic variations), cultural norms and ... social psychology, religions, and soc... ethnic group. There should be semin... writing, and speaking the ethnic langua... there should be seminars dealing with se... and mental health issues of other minorit... search and teaching skills are to be enco... courses should be taught throughout the ... years of training rather than being relega... time.

The specialized training program could ... ent, but in all likelihood it would prob... best as a track system within a general ...

gram. Because all of the residents would have contact with the local ethnic population, some of the special courses should be included in the curriculum for all trainees, with others being elective. For example, a seminar on comparative psychopathology and cultural norms might be required and a course on reading, writing, and speaking the ethnic language be elective. All faculty should be encouraged to participate in these seminars in order to become aware of the difficulties frequently experienced by Asian-Americans. A sensitivity group experience should be mandatory for all residents and faculty to bring into awareness unconscious racial issues that may crop up in supervisory and teaching situations.

While the Asian trainee must be exposed to the clinical experiences required of non-Asian trainees, he or she should participate especially in outreach and aftercare programs. Above all, the trainee's patient load should not be restricted to Asian-American patients; he or she needs to be exposed to a wide variety of individuals with different clinical syndromes and requiring various treatment approaches. The trainee should be encouraged to try innovative therapies for Asian-American patients not fitting into clearly defined Western treatment categories.

TRAINEES AND FACULTY

It is proposed that training programs designated to educate Asian psychiatrists within a general residency have at any one time a minimum of two Asian trainees. Peers learn from each other, apart from the formal instruction they receive, and they need a psychological and culturally similar base support in a new environment. The presence of two or more culturally related Asian trainees, for example, two Japanese-Americans or a Chinese-American and a Japanese-American, would help reinforce their ethnic identification and special training objectives. The trainees should be members of that ethnic minority population served by the training institution or be culturally related to it. If an Asian applicant does not wish to enter this specialized track, he or she should not be counted as one of the two trainees deemed necessary to maintain such a program but should be considered instead as a regular resident.

There must be an adequate number of Asian faculty. I suggest that there be a minimum of three key Asian faculty, consisting of a social scientist and two psychiatrists. One psychiatrist should be a significant figure in the didactic teaching program and the other a clinical supervisor. Part-time Asian faculty and consultants should be involved to further strengthen the didactic and clinical teaching. Being an Asian should not be sufficient in itself to qualify the individual as a key faculty member for the special program. The person must know the cultural, social, and philosophical aspects of his or her ethnic heritage; be able to communicate in the language; and have worked with Asian-American patients and community groups. Outside Asian faculty should be invited to teach in this specialized program. Because it may be difficult to find within a single institution sufficient, qualified Asian faculty, it is essential to engage visiting consultants from other geographic locations in order to provide the program with breadth and depth.

It is important that expert non-Asian faculty also be involved in teaching and supervision. Other faculty not directly involved with the special curriculum or clinical track should be encouraged to attend these seminars and case conferences in order to prevent a sense of fragmentation of the general training program and isolation of the Asian trainees. The resident in the training program for Asian psychiatrists should be regarded in the same light as the fellow in child, forensic, community, or research psychiatry who is expected to possess a sound grounding in basic psychiatry on top of which he or she chooses to superimpose additional, specialized interests.

LOCATION, FISCAL CONSIDERATIONS, AND PROGRAM VIABILITY

The institution should be significantly involved in rendering psychiatric services and readily accessible to a large Asian-American population. An institution located in a large geographically identifiable area, such as a Japantown or Chinatown, in the midst of a predominantly non-Asian community would be more suitable as a training site, than, for example, an institution in Honolulu, where the Asian-American population is the majority. According to the U.S. Bureau of Statistics, 44.1% of the population in Honolulu in 1970 was of Japanese descent. It would also be undesirable to locate a training program in an area where the ethnic population has acculturated into the general population with little influx of recent Asian immigrants and which does not typify the plight of Asian-Americans in large West and East Coast cities.

One or more ethnic training tracks may be situated in a training institution located, for example, in the San Francisco Bay area, where there are significant Chinese, Japanese, and Korean populations. The requirements for each ethnic training program should be maintained whenever possible, for despite many similarities, there are significant differences and needs among the groups. In addition, the ethnic training programs should be multidisciplinary to include training for Asian psychologists, psychiatric nurses, and social workers within the same institution. For this reason these programs should be in institutions that are affiliated with medical schools or universities.

It can be anticipated that the establishment of a "separate but equal" specialized residency training program that focuses on minority groups will draw protests from certain factions of the psychiatric community, which object to the implication that racism and discrimination exist within our profession. My ex-

perience as a psychiatric educator and frank discussions with Asian and non-Asian colleagues indicate that it is time that we address the issue of psychiatric education for all of the minorities. Unlike the black and native American psychiatric applicants who are now much sought after by training programs, Asian candidates have been ambivalently viewed as a glut on the market and yet desired as a cost-accounting measure for institutional service needs. Their educational concerns have been neglected, and as a consequence they have suffered personally and professionally; most of all, the Asian-American patients have lost out in the long run.

Implementing these training programs will be costly. Although close attention must be paid to the current epidemiological studies to justify the funding of such programs, vigilance must be exercised to ensure that their initiation is not unduly delayed. According to Okura (21), during the period 1968–1972 a total of $50 million was allocated to black and Spanish-surnamed trainees, while not a single cent was spent on Asian-Americans.

Another compelling reason for the establishment of training programs for Asian psychiatrists is the Health Professions Educational Assistance Act of 1976 (Public Law 94-484), which became effective on January 10, 1978. Foreign medical graduates will have to limit their stay in the United States to two years, and all exchange visitors must return home for two years before applying for permanent resident status. Over 70% of all foreign medical graduates were Asian, according to a 1972 HEW report (22), and now the majority of Asian psychiatrists in this country are foreign medical graduates. More than ever, the opportunity now exists to blend Western dynamic psychiatry into an appropriate cultural context for export to Asian nations. For this we need specialized training programs. Finally, skepticism has been expressed about the long-range needs for specially trained ethnically oriented psychiatrists. The assimilation and acculturation of Asians into American society have been slow and historically much opposed processes. The "melting pot" dream has not worked for Asians. In addition, there has been a phenomenal rise in the Asian population in this country because of increased immigration in the past few years from Korea, the Philippines, China, and more recently, Viet Nam. It is projected that by 1995 the Asian-American population will rise to 3 million. Mental health resources have been underutilized by Asian-Americans, and the demand for appropriate and effective psychiatric services will not be s[illegible] long time.

EDITORIAL

Children of an Idle Brain?

UNLIKE THE fabled vicar who "trod the strait and narrow path between good and evil," students of the dream have generally been divided into two opposing camps. Freud's extensive review (1) of the nineteenth-century literature well documented the polarization between those who disparaged dreams as an anarchy of meaningless images arising from a brain whose higher functions were inoperative during sleep and those who saw in them a creative force giving rise to knowledge inaccessible to the rational waking mind.

Freud's own contributions to the understanding of dreams need not be belabored here. Suffice it to say that (as every educated twentieth-century man and woman knows) he viewed them as the "royal road to the unconscious"—as the symbolic, usually disguised expression of basic human wishes and needs taking their origin from the earliest phases of the individual's life. However, until the posthumous publication of the "Project for a Scientific Psychology" (2) in the 1950s, it was not generally recognized that Freud was from the start concerned with the neurophysiology underlying psychic processes, including dreaming. The fact that he very early on abandoned the attempt to create a neurological model and focused on the psychological aspects of dreaming determined the cast of analytic thinking for decades to come.

The concept that dreams had a method and order of their own and that their meaning could be fathomed by analysis has not been significantly challenged until recently. In the last two numbers of volume 134 of the *Journal*, Drs. J. Allan Hobson and Robert W. McCarley (3, 4) took serious issue with the analytic view of dreams and dreaming. They not only pointed out that Freud's neurological model was archaic in the light of modern knowledge of the brain's function, but they provided evidence that dreams were after all merely the senseless, random accompaniment of the autonomous electrical activity of the sleeping central nervous system.

If controversy—sharp, critical, intelligent controversy—is an editor's fond desire, his dreams came true. The two papers in question provoked more letters to the Editor than the *Journal* had ever received before. Subsequently published, these were merely the opening salvo of response, and the opposing forces, having marshalled their arguments, now return cannon fire for cannon fire in the form of two articles appearing elsewhere in this issue. Dr. Gerald W. Vogel aims his sights at the neurophysiological model proposed by Drs. Hobson and McCarley, suggesting that their hypothesis is not fully supported by what is known about the dreaming brain. Dr. Anthony L. LaBruzza, pointing to the fundamental irreducibility of psychological and physiological concepts and language, one to the other, argues that Hobson and McCarley's *physiological* formulations of dream processes have no logical bearing on the truth or falsity of the *psychological* understanding of dreams and their meaning.

The battle is joined. We are hopeful that, given a forum, scientific dialectic will lead to a reasonable synthesis. Meanwhile, safe in his foxhole, the Editor will remain neutral; he promises to give equal time to both camps and to cut the logomachy short when it begins to pall.

BRIEF COMMUNICATIONS

An Alternative View of the Neurobiology of Dreaming

BY GERALD W. VOGEL, M.D.

The author critiques the recently proposed activation-synthesis hypothesis about the origin and formation of dreams. Many findings do not support the new hypothesis that specific pontine physiological processes, rather than mental processes, instigate dreams and produce their distortion. First, dreaming often occurs in the absence of the pontine processes. Second, forebrain activity (which can have mental correlates) is crucial to the instigation and maintenance of dreaming sleep. Finally, activity of the proposed pontine dream generator, which is claimed to cause dream distortion, is not reliably accompanied by dream distortion.

TWO PAPERS by Hobson and McCarley have integrated a vast array of recent neurophysiological findings to propose a new, non-Freudian theory of dreaming, the activation-synthesis hypothesis (1, 2). The crux of the hypothesis is that physiological processes rather than psychological processes are the primary instigators of dreams and are the primary determinants of their formal characteristics (viz., distortion, bizarreness, discontinuity, and incoherence). Since Freud proposed that psychological processes instigated dreams and determined their formal characteristics (3), Hobson and McCarley concluded that the recent neurophysiological findings refute Freud's dream hypothesis.

This paper represents an alternative to these views of Hobson and McCarley. I will present evidence that their papers did not consider and that I interpret to be inconsistent with the activation-synthesis hypothesis. Furthermore, on methodological grou[nds] that all of the evidence which modern ne[urophysiology] can provide does not and cannot refute [Freud's] dream hypothesis.

Dr. Vogel is Director, Sleep Laboratory, Georgia Mental Health Institute, 1256 Briarcliff Rd., N.E., Atlanta, Ga. 30306. He is also Professor of Psychiatry, Emory University School of Medicine, Atlanta, Ga.

The author wishes to thank Dr. Alan Rechtschaffen, University of Chicago, for his helpful comments.

MAJOR PROPOSITIONS OF THE HYPO[THESIS]

The validity of the activation-synt[hesis]—and its corollary, the refutation of F[reud's] hypothesis—rests on the evidence suppo[rting] main propositions (1). These propos[itions] stated as follows:

1. Dreaming occurs only during a c[ertain] physiological state known as the desyn[chronized] state or D sleep.

2. Pontine FTG cells are the sole gener[ators] D state. Augmentation of FTG discharge [is] necessary and sufficient condition for [the] of the D state. Dreaming is produced by [the] activation of the forebrain, which creat[es] using stored memories to make sense of [the] originated in the pons. The dream, ther[efore] synthesis of a pontine activation pat[tern] vious experience—hence the term "[activation-] thesis." Because the neural mechanism [of] the D state is located in the pons and is [genetically] preprogrammed, metabolically determi[ned] dreaming is instigated by a physiolog[ical] Since Freud proposed that dreams w[ere] psychological processes such as uncon[scious] tive wishes, his theory of dreams must [be]

3. The formal characteristics of dream[s] bizarreness, discontinuity, and incoh[erence] caused by the temporally random activ[ation] forebrain by the FTG cells. Barraged [with] stimulation, the forebrain "does the b[est] job" to make sense of such randomness. [Hence] dream distortion, incoherence, etc. Hence [the] tortion is caused by a physiological pro[cess] activation) rather than a psychological pr[ocess]

the defensive need to disguise or censor unacceptable wishes, as proposed by Freud.

EMPIRICAL CRITIQUE OF THE HYPOTHESIS

What Causes Dream Distortion

I will now examine evidence and methodologic issues related to the activation-synthesis hypothesis that were not considered by Hobson and McCarley. I begin with the proposition that dream distortion is caused by a partially random discharge of neuronal units (FTG cells) in the pontine D state generator.

Hobson and McCarley present no evidence to support this proposition. Indeed, it is an assumption without empirical support. We have no evidence that "disordered" meaning is caused by a disordered (temporally random) discharge pattern of individual neurons. In more general terms, we do not know the neural correlates of particular sequences of mentation, ordered or disordered. We also do not know that the orderliness of mental sequences is determined by the pattern of hindbrain stimulation of the forebrain. It is possible that mentation is relatively independent of hindbrain stimulation and is primarily determined by the response characteristics of the forebrain. In any case, our ignorance about these issues is very great. In view of such ignorance, the claim that disordered (incoherent) meaning is caused by disordered (random) discharge of individual pontine cells appears to be based on verbal similarity rather than empirical findings. Indeed, the empirical findings do not support this claim.

Contrary to the hypothesis, the empirical correlation between irregular (phasic) discharge bursts of the proposed pontine generator and dream distortion is very weak. Relevant studies report that dream distortion, bizarreness, and discontinuity are unrelated or only weakly or unreliably related to indicators of the generator's phasic discharge bursts (4–6). Furthermore, based on the high frequency of random phasic bursts of the generator, the hypothesis would predict that distortion, bizarreness, and incoherence are very frequent characteristics of dreams. However, contrary to the hypothesis, D state dreams usually contain realistic imagery, concern banal everyday events, and display remarkable thematic coherence (7–10). Thus, the correlational evidence does not support the claim that dream distortion is caused by the partially random discharge of a pontine D state generator. Put directly, D state dreams simply do not resemble that kaleidoscopic barrage of unconnected images one would expect from a random generator of mentation.

Furthermore, the activation-synthesis hypothesis cannot explain the remarkable coherence of most dreams by shifting its emphasis from the disordering effect of random hindbrain stimulation to the ordering effect of a forebrain synthesizing response. Such an explanation would mean that although the hypothesis has not predicted dream coherence, it could, post hoc, conveniently invoke just the right amount of synthetic activity to explain the observed coherence of any dream. With such explanatory agility, the hypothesis would be compatible with all degrees of dream coherence but would predict none. In that case, the hypothesis would have no testable empirical consequences and would therefore be empirically meaningless.

The "Dream State Generator"

Next, I will examine evidence on an alternative to the proposition that the "necessary and sufficient" generator of the D state is a pontine mechanism in which the FTG neurons are the specific D state executors. Support for this proposition comes mainly from animal transection, lesion, stimulation, and unit recording studies. My examination of these studies leans heavily on Siegel's recent critical review of the neurophysiology of D state generation (11) and on the related work of Siegel, McGinty, and Breedlove (12–14).

Consider first the transection studies. Cats, decerebrate at the pontine or pontomesencephalic level "exhibit all the brainstem components of the D state . . ." (11). Furthermore, there is no D state in the permanently isolated forebrain of the cat (15). Clearly, the brain stem—and not the forebrain—contains structures whose activity is a necessary and sufficient condition for the brain stem components of the D state. However, these results do not rule out the possibility that in the intact animal, forebrain structures interact with the brain stem D state structures in such a way that the forebrain is crucial for D sleep. This possibility is supported by the McGinty and Sterman finding that lesions of the basal forebrain (which left the brain stem intact) ". . . totally eliminated (the D state) for periods of several weeks" (16). The work of Villablanca and Marcus (17, 18) more directly supports the crucial importance of the forebrain for the D state. These investigators studied sleep and wakefulness over several months in chronic diencephalic cats, i.e., cats without neocortex, striatum, and rhinencephalon. In such cats, non-D sleep was reduced to 1/8 of that in control (nonlesioned) cats, and D sleep was reduced proportionately much more to ". . . less than 1/20 of the controls. In fact D sleep was completely absent in 10 out of 48 sessions (24 hours of observation) while non D sleep was never absent. . . . The normal cyclic distribution . . . of the remaining non D sleep and D sleep could not be demonstrated" (17, pp. 357–358). Moreover, according to my calculations from the other Villablanca and Marcus data (17), the diencephalic cats averaged 2 episodes of D sleep per 24 hours, while the controls averaged 31 longer episodes of D sleep per 24 hours. This evidence indicates that, contrary to the activation-synthesis hypothesis, the forebrain plays a crucial role in the instigation, maintenance, and timing of most episodes of D sleep. Evidence from the Villablanca and Marcus study also indicates that the forebrain affects its own activation pattern during D sleep because the frequency of rapid eye movements (or phasic discharges) during the D state was higher in the chronic diencephalic cats than in the intact control

(17). In the intact animal, the forebrain exerted an inhibitory influence on the D state phasic discharge pattern of the hindbrain. Therefore, contrary to the activation-synthesis hypothesis, the hindbrain activation pattern is not autochthonous, and the forebrain is not simply a passively responding slave of the hindbrain. Rather, the forebrain influences the hindbrain activation pattern. As Villablanca and Marcus put it, "the present finding in 'diencephalic' animals necessitates a revision of [the] concept (that rostral structures do not exert much control over caudal brain stem sleep mechanisms) . . ." (17). "Our hypothesis of the direct, although complex, descending forebrain influence controlling the lower brain's sleep wakefulness structures appears to fit the available data better" (19).

Pontine lesions that eliminate the D state, as in the transection studies, have been interpreted to indicate that the brain stem contains the necessary and sufficient generator of the D state. However, Siegel's critical review offers a different conclusion (11). Siegel emphasized the many shortcomings of the lesion technique when applied to the brain stem. In particular, the specific effects of a localized brain stem lesion cannot be separated from the strong nonspecific effects of the lesion. The latter include serious morbidity (often leading to death), destruction of surrounding blood supply, and death or damage of neighboring neurons and neuronal fibers—all of which occurrences have adverse effects on remote structures. Thus, elimination of the D state by pontine lesions (although consistent with the theory that pontine structures are necessary for D sleep) does not necessarily imply that in the intact animal the pons contains structures sufficient for generation of the D state.

Similar conclusions may be reached from stimulation studies. Although pontine stimulation can instigate the D state, "stimulation of a variety of structures including cortex [20], vagal nerve [21], and the visual system [22] can induce the [D state]" (11). Thus, structures outside the brain stem, including many cortical areas, can instigate the D state.

Finally, on the basis of unit recording studies, Hobson and McCarley have proposed an ingenious pontine mechanism to explain the alternate generation of non-D sleep and D sleep (23, 24). According to these workers, two pontine neuronal groups, a D state inhibitor and a D state generator, reciprocally interact to produce the alternation of non-D sleep and D sleep. The pontine FTG cells are the specific neurons whose augmented activity generates the D state. Hobson and McCarley originally suggested that these neurons were the D state generator because, among other properties, the FTG met the crucial selectivity test, i.e., their firing rates increased selectively during the D state and decreased in the absence of the D state (during wakefulness and slow sleep) (23, 24). More recently, considerable controversy has developed among neurophysiologists about whether the FTG neurons meet the selectivity criterion (11-14, 25). I will present evidence that they do not. In doing so, I am not criticizing the reciprocal interaction model. My po[illegible] cerns the anatomical location of the D sta[illegible] not the mechanism responsible for the alt[illegible] and non-D sleep.

Evidence from two independent labora[illegible] gations indicates the original finding that [illegible] selectively during D sleep was an artifact [illegible] nal experimental procedure (11-14, 25). [illegible] ity for D sleep was originally found in ca[illegible] placed in head restraints to prevent hea[illegible] and to maintain the location of the rigid re[illegible] trodes in the brain (23). Using mo[illegible] trodes, Siegel, McGinty, and Breedlove [illegible] found that in cats without head restrai[illegible] rates of FTG cells during waking hea[illegible] were as high as during D sleep. Ver[illegible] tially the same observation in rats (25). [illegible] cies, the waking FTG discharge during [illegible] not instigate the D state. Agreeing w[illegible] McGinty, I interpret this evidence to i[illegible] mented FTG discharge is not selectiv[illegible] D state and that FTG cells are not the [illegible] D state.

Furthermore, the evidence does not [illegible] expected defenses of the FTG cells as D[illegible] ators. Specifically, there is no evidence [illegible] portion of FTG cells firing during con[illegible] movements is different from the proporti[illegible] ing D sleep, 2) that the firing rates of FTG [illegible] during waking than during D sleep, an[illegible] waking FTG discharge generates only p[illegible] state, such as the phasic or motor com[illegible] Thus, considering all aspects of the issu[illegible] along with Siegel and McGinty, that the [illegible] not meet the selectivity criterion and are n[illegible] ators of D sleep or of any component [illegible] as Siegel points out, despite an intensiv[illegible] pontine neurons have been found that se[illegible] during D sleep (11).

In summary, transection, lesion, stim[illegible] unit recording studies suggest that in the [illegible] both the hindbrain and the forebrain par[illegible] generation of the D state. The hindbr[illegible] structures whose activity is necessary for [illegible] However, contrary to the activation-sy[illegible] esis, in the intact animal the forebrain [illegible] role in the instigation, timing, maintenan[illegible] vation pattern of most episodes of D sleep [illegible] instigators of most D state dreams and [illegible] nants of their formal characteristics are [illegible] processes in the brain stem, where mu[illegible] has no psychological correlates. The fore[illegible] activities can have psychological correlate[illegible] a role in the generation of the D state. [illegible] opens the possibility for psychological ev[illegible] ing and formally shaping D state dreams.

Formal Dream Characteristics

Finally, I will examine evidence about t[illegible] proposition of the activation-synthesis [illegible]

that bizarre, vivid, visual, hallucinated dreaming occurs only during the D state. This proposition is strongly contradicted by empirical data. Studies from different laboratories have found that dreams for all practical purposes indistinguishable from D state dreams occur in the absence of the D state (26-28). For example, during sleep onset dreaming is very prevalent: 50%-70% of awakenings from certain non-D state, sleep-onset EEG stages result in the report of a dream. When compared with D state dreams, sleep onset dreams are not significantly different in bizarreness, length, manifest sexual content, manifest aggressive content, hedonic tone, or dreamlike quality (27, 28). Furthermore, instigators of sleep onset dreams are more closely related to psychological variables than to physiological variables such as EEG stage (27, 29). Dreaming also occurs frequently throughout the non-D sleep of light sleepers (30).

The finding that dreams similar to D state dreams occur frequently in the absence of the D state has two implications. First, the unique physiology of the D state does not explain the instigation or formal characteristics of the non-D state dreams. Second, the similarity of D state and non-D state dreams makes it unlikely that unique D state neurophysiology determines the characteristics of D state dreams. Rather, the similarity of dreams in different states suggests that some properties common to all the dream states determine dream characteristics. We do not know what these properties might be. One plausible speculation is that forebrain response characteristics during sleep are common to all dream states and forebrain activation sources are unique to the different dream states. That, at least, would be consistent with most of the neurophysiological evidence presented above.

Let me clarify the relationship between activation sources and response characteristics with an analogy. Imagine a town with several different independent sources of electrical power. Each night, the temporospatial pattern of lighting will be independent of the power source but will depend on the usual habits of the town's inhabitants and on their unique needs of that day. The power sources obviously represent the forebrain activation sources, the inhabitant's usual habits represent the neural correlates of personality traits, and the unique day's needs represent the neural correlates of recent experiences. In other words, my suggestion is that state generators—like the D state generator—permit dreaming to occur but do not instigate the actual content or determine its characteristics. These, being similar in all dream states, are functions of the response characteristics of the forebrain. This would suggest that psychological phenomena, which are correlates of forebrain activity, can instigate actual dream content and determine its formal characteristics.

Summary of Empirical Critique

This completes the critical review of the activation-synthesis hypothesis. As a whole, the evidence does not support its three propositions. First, dreaming is not limited to the D state. Second, in the intact animal pontine structures, although necessary for D sleep, are not sufficient to account for the generation of most D sleep episodes. The forebrain is also necessary for the instigation, maintenance, and timing of most D sleep episodes. Hence, contrary to the propositions of the activation-synthesis hypothesis, forebrain neural structures with possible psychological concomitants are involved in the instigation of the D state. Third, the correlational evidence contradicts the claim that the formal characteristics of dreams are related to phasic pontine activation. Thus, the evidence does not support the crux of the hypothesis, that (pontine) physiological processes rather than psychological processes instigate dreams and determine their formal characteristics. Furthermore, such an unsupported neurophysiological theory cannot be a sound refutation of Freud's dream hypothesis.

METHODOLOGICAL CRITIQUE OF THE HYPOTHESIS

I have a final comment about Freud's dream theory that is not related to the soundness of the neurophysiological attack on it. Here, I want to show that purely neurophysiological data—such as that used in the activation-synthesis hypothesis—cannot refute a purely psychological theory such as Freud's.

A psychological theory asserts a reliable relationship among psychological variables. Physiological variables can be used to test this psychological relationship only if the physiological variables are empirically reliable correlates of the relevant psychological variables. Conversely, we cannot know that physiological variable A is not the correlate of psychological variable B until we empirically determine the correlation between A and B. Applied to the particular case of dream theory, we cannot know, for example, that pontine activation of the forebrain is not the neural correlate of emergent, primitive, unconscious wishes until we empirically determine the correlation between pontine activation and emergent, primitive, unconscious wishes. That determination has not been made. Hence, we cannot use the physiological variable, pontine activation, to indicate the absence of unconscious wishes. Put in general terms, neurophysiological variables cannot be used to test a psychological theory of dreams (such as Freud's) when the correlation between the relevant psychological variables and the relevant physiological variables is unknown.

Furthermore, even when the relevant psychophysiological correlations are known, the use of physiological variables to test a psychological theory provides only an indirect test of the theory. A direct test would involve only the psychological variables. In the case of Freud's dream theory, a direct psychological test has yet to be made. In a recent detailed examination of the empirical foundation of Freud's dream the-

ory, I concluded that in principle the theory consisted of a structured set of testable but as yet untested hypotheses (31). That a direct psychological test of a psychological theory is more valid than a psychophysiological test can be seen from the following. If the direct psychological test reliably supported the psychological theory and the psychophysiological test did not, we would conclude that the physiological variables were not valid indicators of the psychological variables. This again supports the conclusion that purely neurophysiological data such as that used by Hobson and McCarley cannot refute a purely psychological theory such as Freud's.

CONCLUSIONS

In summary, Hobson and McCarley have provided us with the first theory that genuinely attempts to integrate the recent discoveries in the neurophysiology of dreaming with the peculiarities of dream mentation. One important implication of this theory is that its neurophysiological foundation appears to refute Freud's hypothesis that psychological phenomena instigate dreams and determine their formal characteristics. However, a critical review of additional neurophysiological and psychophysiological evidence indicates that the new theory is not consistent with a number of findings and cannot be used to refute a psychological theory of dreams such as Freud's.

The Activation-Synthesis Hypothesis of Dreams: A Theoretical Note

BY ANTHONY L. LABRUZZA, M.D.

The author examines Hobson and McCarley's activation-synthesis hypothesis of dreams from the point of view of theory construction and the logic of science. After reviewing pertinent literature, he concludes that modern science has not yet established a well-defined mind-body isomorphism. Therefore, conclusions about the psychological meaning and motive of dreams cannot validly be drawn from neurobiological data.

RECENT RESEARCH in the neurobiology of dreaming sleep by Hobson and McCarley has led to their proposal of an activation-synthesis hypothesis of the dream process (1, 2). Technical advances have allowed investigators to study desynchronized (D) state control in cats by recording from individual neurons in various parts of the cat brain as the sleep cycle progresses. The result has been an impressive and scholarly enhancement of our knowledge of the neurophysiology of sleep and dreaming. In essence McCarley and Hobson have shown that the D state is generated by autochthonous, periodic activation of pontine generator cells with elaboration of the pontine neuronal stimulus by the perceptual, conceptual, and emotional structures of the forebrain during sleep. Unfortunately, these same authors attempt to extend their extensive neurobiological findings to psychoanalytic dream theory without sound logical justification.

The popular press (3, 4) has capitalized on the activation-synthesis hypothesis to make it appear that Freudian dream theory has been "scientifically" invalidated. It is as if we can now rest easy, for our secret, "repressed" wishes can no longer be discovered in the analysis of our dreams. Such theoretical conclusions are unjustified on the basis of McCarley and Hobson's findings. The purpose of this article is to critique Hobson and McCarley's theorizing and to elaborate the need for careful conceptual, logical, and theoretical analysis in drawing conclusions from neurobiological data. The theory of dreams and dreaming will be taken as a model. I have not attempted an exhaustive discussion or literature review; rather, I will examine some fundamental issues of theory building and evaluation.

Dr. LaBruzza is Instructor, Department of Psychiatry, Yale University School of Medicine, P.O. Box 12A, Yale Station, New Haven, Conn. 06520.

FROM PHYSIOLOGY TO PSYCHOLOGY

Freud was well aware of the difficulties in arguing from principles of brain physiology to principles of psychological functioning. Although he set out in the "Project for a Scientific Psychology" (5) "to furnish a psychology that shall be a natural science," he ran into theoretical difficulty that ultimately compelled him to abandon the project. As Strachey explains, Freud "threw over the whole neurological framework" (6) because the neuronal machinery had no means of accounting for the fact of consciousness. Having abandoned his attempt to develop a physiology of the mind, Freud sought in "The Interpretation of Dreams" (7) to define a purely psychological model of mind based on "analogies" and "giving free rein to our speculations." Freud explicitly stated his point of departure: "I shall carefully avoid the temptation to determine psychical locality in any anatomical fashion. I shall remain upon psychological ground . . ." (7). Implicit in Freud's remarks is his recognition of the fundamental principle that "different levels of scientific explanation may involve essentially different frames of reference, and each level may therefore require a different appropriate language" (8). Peterfreund gives a homely illustration of this principle when he points out that if Tom loves Jane ("love" belonging to the language of persons), one does not say that Tom's brain loves Jane's brain, and so on (8).

McCarley and Hobson ignore this principle when they claim that the primary motive for dream language cannot be disguise because the firing of cells in the pons is motivationally neutral. In their own words, "The *primary motive* for the dream language and dream process cannot be disguise if the prime force of dreams is not an instinct or represented 'wish' in need of disguise" (1, p. 1219). Such faulty logic and conceptual unclarity are surprising in an otherwise carefully reasoned and scholarly report. The authors are precise in defining a dream as "a *mental* experience, occurring in sleep . . ." (2, emphasis added). Nonetheless, they frequently fail to distinguish between the dream state (a neurophysiological process) and dreaming as a mental (subjective) experience. There is no objection to their claim that something is happening in the nervous

0002-953X/78/0012-1536$0.40 © 1978 American Psychiatric Association

system which corresponds to the mental process of dreaming; but that "something" cannot be described in the language of dream meaning and motive, nor can the psychological purpose of a dream be explained in terms of the firing of cells of the pons or forebrain. In contrast to Hobson and McCarley, Freud was firm in his resolve to allow "psychology the right to account for its most common facts . . . by its own means" (9). Horton suggests that Freud's resolve in this matter had to do with "the epistemological judiciousness of mixing frames of reference, of throwing together, willy-nilly and chaotically, the immediate experience of brain cuttings and pathology slides with the immediate experience of emotions, thoughts, and actions" (10, p. 516).

The net effect of such injudicious mixing of frames of reference is the unwarranted implication that Hobson and McCarley's neurobiological discoveries will logically necessitate major revisions in psychoanalytic dream theory. As previously mentioned, reports in the popular press have already picked up on this implication, claiming that the activation-synthesis hypothesis "discounts Freud's psychoanalytic notion of dreams . . ." (3) and that "if the origin of dreams is adequately accounted for by a physiological mechanism, there is no need to hypothesize a psychological motive for dreaming" (4). Statements such as these are glaring examples of the confusion of independent logical orders and need no further comment.

It is noteworthy, however, that psychoanalytic theorists have long been familiar, implicitly or explicitly, with the notion that, logically considered, repressed wishes cannot physiologically initiate the dream state (8, 10–16). Yankelovich and Barrett (11) traced back almost two decades the theoretical misgivings about Freud's theory of forces as opposed to his theory of meanings. It is true that Freud used the term "wish" to represent both a meaning and a physical force, but no serious modern theoretician would make such a claim. In an odd way, McCarley and Hobson are merely confirming what has been accepted by knowledgeable theoreticians for many years: it is not valid to move freely between independent logical systems of description and explanation. One cannot add apples and oranges without appealing to a superordinate concept such as fruit. Likewise, wishes cannot trigger cells, and cells firing in the pons cannot determine the meaning and motive of dreams.

MIND-BODY ISOMORPHISM AND THEORY CONSTRUCTION

In attempting to address the nature of theory construction, we cannot avoid coming face to face with the perennial mind-body problem. How can we reconcile subjective experience with concomitant objective measurements? McCarley and Hobson have provided us with the physiological concomitants of the subjective experience of dreaming. We have seen how they ran into difficulty when they blurred [illegible] between the distinct logical realms of me[illegible] tive on the one hand and causality on t[illegible] mulations about the meaning and motive [illegible] wish fulfillments (or archetypal images[illegible] serve to order the subjective experien[illegible] cally independent of formulations in [illegible] jective experience is treated objective [illegible] causality of the dream state by pontine [illegible]

In short, there exist two discrete [illegible] dreams and dreaming, the neurobiolo[illegible] chological, the "objective" and the [illegible] These two approaches must be coordinat[illegible] multaneously with the logically indep[illegible] explanation. Thus, mind and brain (or [illegible] be treated as two distinct orders, each [illegible] peculiar language, conceptualizations, [illegible] abstraction; to treat them otherwise [illegible] and conceptual unclarity. There is, as y[illegible] ordinate framework or well-defined [illegible] unites these realms of mind and body [illegible] the history of science, data about the [illegible] functioning of psyche and soma are the [illegible] ance, coincidence, and correlation. Cros[illegible] mon explain that the only way to use the[illegible] ent models simultaneously is

> by coordinating them in their application t[illegible] unity of the phenomena under study. For ev[illegible] chophysiological research we work with [illegible] variants, such as the physiological cor[illegible] ported experience. The coordination is an [illegible] ity, which is not equivalent to prov[illegible] explanation for experience and physiolo[illegible] establish a concordance or parallelism [illegible] something about correlations. Only some [illegible] framework, yet to be discovered, could pr[illegible] cal system in which both aspects could be [illegible] (cf. Langer, 1967). In current dream res[illegible] ample, there is a high correlation betwee[illegible] rapid eye movement sleep (REMs). How[illegible] understanding of the *meaning* of dreams is [illegible] the clarification of the REM mechanism [illegible]

In summary, then, analysis of McCar[illegible] son's attempt to construct a theory of [illegible] dreaming has led to a number of im[illegible] tions. There is, to be sure, a general cons[illegible] psychiatrists that mind and body (or [illegible] tute a functional unity. However, to [illegible] psychosomatic issues one must account [illegible] two logically independent realms. One re[illegible] with mind, meaning, motive, and subje[illegible] ence; the other, with brain, body, causalit[illegible] tive measurement. Each realm has its own [illegible] guage, concepts, levels of abstraction, [illegible] and means of determining veridicality.

Relevant to these concluding remarks [illegible] stein's hypothesis of empirical parallelis[illegible] "every phenomenal event is correlated [illegible] rophysiological event" (14). This notion [illegible] parallelism implies that "statements ab[illegible]

correlated events are also correlated; but they are not translatable to one another" (14). Phenomenal and neurophysiological statements belong to different languages and cannot be translated because translation involves transposing without change of reference a statement in one language to a statement in another. By now the reader should be amply aware of the confusion that arises when Hobson and McCarley attempt to translate statements about cells to statements about dream language without regard for the change of reference involved. Further, there is not currently any way to translate statements about cells and dream motive into a common superordinate language. As Reiser observed, "There is no way to unify the two by translation into a common language, or by reference to a shared conceptual framework, nor are there as yet bridging concepts that could serve, as Bertalanffy suggests, as intermediate templates, isomorphic with both realms" (15, p. 479).

It was McCarley and Hobson's assumption of a mind-body isomorphism "in a less exact sense" (1) that got them into theoretical difficulty. The term "isomorphism" has an exact meaning. Either there is an isomorphism or there is not. To make deductions from an isomorphism in a less exact sense is to try to have it both ways. This approach has no foundation in the logic of science.

If by isomorphism "in a less exact sense" McCarley and Hobson mean the use of "analogies" and what Freud termed "giving free rein to our speculations" (7) to generate hypothetical constructs, then they should also agree with Freud that such methodology is "only intended to assist us in our attempts to make the complications of mental functioning intelligible" (7). To speculate from analogy and evocative metaphor is a time-honored tradition for generating scientific hypotheses, but in no way does it constitute scientific proof or explanation as McCarley and Hobson imply. As it now stands, the activation-synthesis hypothesis of the dream process is an impressive theoretical statement about the neurobiology of the dream state; however, its extrapolation to psychoanalytic dream theory is mere speculation, albeit fascinating speculation, and represents a deviation from basic principles of sound theory construction.

Comparison of the Incidence and Severity of Extrapyramidal Effects with Fluphenazine Enanthate and Fluphenazine Decanoate

BY JOHN KANE, M.D., FREDERIC QUITKIN, M.D., ARTHUR RIFKIN, M.D., AND DONALD F. KLEIN, M.D.

Forty-nine schizophrenic outpatients stabilized on oral antipsychotic medication and procyclidine received 12.5 mg or 18.75 mg of fluphenazine enanthate or fluphenazine decanoate and were examined for extrapyramidal side effects one and two weeks later. Extrapyramidal side effects were present in 30 patients (61%) but were clinically significant in only 11 (22%). Fluphenazine enanthate produced more clinically significant extrapyramidal symptoms, particularly akathisia, than did fluphenazine decanoate.

A SIGNIFICANT PERCENTAGE of schizophrenic outpatients do not take medication as prescribed. Estimates of noncompliance (1–4) vary from 32% to 63%. Long-acting, injectable phenothiazines offer a partial solution to this problem. However, a major disadvantage associated with fluphenazine enanthate, the first long-acting injectable preparation, is its tendency to produce extrapyramidal side effects (EPS). With the introduction of fluphenazine decanoate it became important to compare these agents for the frequency of side effects. Five studies (5–10) have appeared in the literature contrasting the incidence of EPS with fluphenazine decanoate and fluphenazine enanthate.

Kurland and Richardson (5) compared fluphenazine decanoate and fluphenazine enanthate in 19 chronic schizophrenic patients, who ranged in age from 23 to 53, in a 12-week, random-assignment, double-blind crossover study. No prophylactic antiparkinsonian medication was given. It is not clear whether or how often patients were systematically examined for EPS. Five patients developed evidence of EPS, 3 on fluphenazine enanthate and 2 on fluphenazine decanoate. The authors found no significant difference between these agents in producing EPS. However, it is difficult to interpret this study because of variations in injection intervals and lack of clarity regarding the time in which EPS were assessed.

Keskiner and associates (6) reported on schizophrenic patients (age range, 26–51) who received fluphenazine decanoate at two-week intervals in doses ranging from 2.5 mg to 75 mg. Fluphenazine decanoate treatment lasted from 12 to 78 weeks (average, 42 weeks). Single-blind fluphenazine therapy was replaced by fluphenazine enanthate administered in equal dosage at the same intervals for a maximum of 12 additional weeks.

Patients were rated (7) monthly for extrapyramidal side effects. Thirteen patients required antiparkinsonian medication during the fluphenazine decanoate treatment. If antiparkinsonian medication was given, it was continued throughout the entire study. This procedure confounded any comparison between fluphenazine decanoate and fluphenazine enanthate. Of those receiving fluphenazine enanthate, 2 required an increase in antiparkinsonian medication and 2 required the initiation of antiparkinsonian medication. The authors found no significant difference between the side effects of the two drugs. It is difficult to interpret these findings, however, because all patients received fluphenazine decanoate first and most were started on antiparkinsonian medication, which was then discontinued during fluphenazine enanthate treatment. Despite this, 4 patients had an increase in EPS when switched to fluphenazine enanthate.

Itil and associates (8) completed a double-blind crossover study comparing the effects of fluphenazine enanthate and fluphenazine decanoate on chronic schizophrenics (age range, 25–51). Procyclidine was administered, 10 mg/day, and the dosage was increased if necessary. Side effects were rated on the Treatment Emergent Symptoms Scale (9).

The total dosage of procyclidine and the mean values of side effects were higher for the fluphenazine enanthate group than for the fluphenazine decanoate group but not significantly so. The use of unusually high starting doses (1 mg/kg) limits the generalizability of the findings.

Grosser (10) studied 61 female schizophrenic patients (23 of whom had been in the hospital for more than a year) randomly assigned double-blind to fluphenazine enanthate or fluphenazine decanoate for 4

weeks. The dosage and injection interval were determined by previous medication levels and clinical criteria. Antiparkinsonian medication was given only on emergence of EPS. Additional major tranquilizers, ECT, and night sedation were administered as necessary. Three of 4 patients requiring additional major tranquilizers were in the fluphenazine enanthate group, but no further details are given.

Grosser found significantly more EPS in the fluphenazine enanthate group. He acknowledged that the baseline level of psychiatric symptomatology was higher in the fluphenazine enanthate group and did not compare dosages. It is possible, therefore, that due to greater baseline psychopathology the fluphenazine enanthate group was placed on higher doses than the fluphenazine decanoate group.

Van Praag and Dols (11) reported on 30 inpatients with various diagnoses in a 4-week double-blind random-assignment study using a single 25-mg injection of fluphenazine decanoate or fluphenazine enanthate. In addition, if a patient's condition warranted it, the treating psychiatrist also administered chlorpromazine in a single-blind fashion. If extrapyramidal side effects were observed, orphenadrine was prescribed openly. It is not clear how or with what frequency patients were examined for EPS. In the first week, orphenadrine was prescribed for 11 of the 17 fluphenazine enanthate patients and 3 of the 16 fluphenazine decanoate patients ($p<.05$). During this period the two groups did not differ significantly in the number of patients requiring supplementary chlorpromazine; therefore, it is unlikely that this could account for the differences in EPS.

A review of the studies comparing the effects of fluphenazine enanthate and fluphenazine decanoate indicates a lower incidence of EPS with fluphenazine decanoate in two studies and no difference in three. Most of these studies have serious methodological flaws. The best designed study (11) reported fewer extrapyramidal side effects with fluphenazine decanoate.

The purpose of our study was to determine if fluphenazine enanthate was more likely than fluphenazine decanoate to produce EPS during the first two weeks after their initiation. Our a priori hypothesis was that fluphenazine enanthate would be more toxic.

METHOD

The subjects in our study were 49 recently discharged schizophrenic patients who were attending an aftercare clinic and were stabilized on oral antipsychotic medication and procyclidine, 15 mg/day. The cohort included 29 men and 20 women, with an age range of 13 to 37. We wished to switch these patients to injectable fluphenazine in preparation for a long-term maintenance medication study and took this opportunity to compare the incidence of EPS with fluphenazine enanthate and fluphenazine decanoate. Informed consent was obtained from all patients.

Treatment Design

Because some earlier reports (10, 12) had indicated a high incidence of EPS with fluphenazine enanthate and fluphenazine decanoate, we began with a conservative regimen: 25 patients were assigned randomly to receive 12.5 mg of either fluphenazine decanoate or fluphenazine enanthate and 2 mg of benztropine mesylate I.M. The other 24 patients received 18.75 mg of either fluphenazine decanoate or fluphenazine enanthate without benztropine mesylate. All of the patients continued to take procyclidine, 15 mg/day, and some patients continued to take a fixed dose of oral antipsychotic medication throughout the study. The decision to continue oral medication was based on clinical judgment. Eleven patients who received fluphenazine decanoate and 13 patients receiving fluphenazine enanthate also took oral antipsychotics. In addition, 3 patients in the fluphenazine enanthate group and 2 in the fluphenazine decanoate group were receiving imipramine at a constant dose throughout the trial and 1 patient in each group was receiving lithium.

There were no significant differences between the groups in average age, sex, or average dosage of concomitant medication.

Evaluation

An examination for extrapyramidal side effects was carried out at baseline, 1 week, and 2 weeks after the initial injection by a physician blind to the type of injection received. All of the patients were examined at baseline. The data were incomplete in 11 patients (22%) due to noncompliance. Ten of these 11 patients missed the 2-week examination. There was no significant difference in compliance between the fluphenazine enanthate and fluphenazine decanoate groups.

Evaluations for extrapyramidal side effects were carried out using 8 items of the Simpson-Angus scale (13): gait, arm dropping, shoulder shaking, elbow rigidity, wrist rigidity, glabella tap, tremor, and salivation, as well as 2 additional items to measure dystonia and akathisia and 2 items to measure akinesia (spontaneity of speech and gestures). Items were rated on a 5-point scale, except the 2 measures of akinesia, which used a 4-point scale.

RESULTS

The results are presented in table 1. Of the 49 patients in the study, 30 (61%) developed detectable EPS. Of these 30 patients, 19 experienced a change of one point on the scale. A change of one on this rating scale is of dubious clinical significance, however; since we were interested in determining if either drug had any potential advantage at all the first statistical comparison involved all manifestation of extrapyramidal side effects, whether of clinical significance or not. No significant difference existed when the drugs were contrasted on the 12 individual items nor between the drug

One-tailed FE.

groups when all 12 items were considered together. In addition, no differences were found when the same drug was contrasted at the two different dosage levels.

Eleven patients (2%) had a change of two or more on any one item (a change that might be clinically significant). When only these 11 patients were considered, a difference did emerge. Of the 26 patients receiving fluphenazine enanthate at either dose, 9 patients (35%) developed significant EPS, but only two (9%) of the 23 patients receiving fluphenazine decanoate did (p=.03, one-tailed FE).

Akathisia was the most frequent clinically significant extrapyramidal side effect. Of 26 patients receiving fluphenazine enanthate, 7 (26%) developed significant akathisia whereas 1 (4%) of 23 patients receiving fluphenazine decanoate did (p=.04, one-tailed FE). We used a one-tailed test because our a priori hypothesis, based on the literature, was that fluphenazine enanthate was more likely to produce EPS.

At baseline, 9 patients had ratings of two or more on one item, which indicates potential clinical significance. Five of these patients had their oral antipsychotic medication discontinued or decreased at baseline. None of the EPS noted caused subjective distress or interfered in any way with these patients' functioning. Five of these patients received fluphenazine enanthate and four received fluphenazine decanoate. Only 1 of them experienced a worsening of the item that was present at baseline. Only 2 of the 9 patients (22%) with EPS at baseline experienced any significant new EPS. This is the same percentage that was found among patients with no baseline EPS. This would seem to indicate that mild EPS are not necessarily a contraindication to starting long-acting fluphenazine.

Of the 18 patients who experienced a 1-point change on any item, 4 had baseline scores of 1 on that item and therefore manifested a rating of 2 at some point. These patients were evenly distributed, 2 in each drug group, and were not included among those considered to have developed clinically significant EPS.

Of the 26 patients receiving fluphenazine enanthate, 9 experienced no extrapyramidal side effects during either week of the study, as did 10 of the 23 patients receiving fluphenazine decanoate. There were 13 patients in the fluphenazine enanthate group and 6 in the fluphenazine decanoate group who ha... symptoms during the first week but ... patients receiving fluphenazine ena... tients receiving fluphenazine decan... pyramidal symptoms in the second we... tient in each group experienced ext... effects during both weeks. DISCUSSION

Our results indicate a relatively high ... EPS with fluphenazine enanthate and ... decanoate, as has been reported. He... studies have not quantified the severity ... measurements indicate that most are of ... cance. Even in those cases where a cha... more occurred on any one item, the sy... usually transient and none significantly ... the patient's functioning or precluded ... of the same or even larger doses after the ... experience with 300 patients in long-term ... medication studies or in transition for ... only 7% have been unable to continue ta... ing fluphenazine decanoate because of ... side effects.

There are several factors that may ... to the low incidence of functionally signif... served in this population. All patients ... phylactic antiparkinsonian medication, so ...

the occurrence of EPS that it did not prevent. Some studies (14–16) have suggested that the routine use of prophylactic antiparkinsonian medication is of questionable value even with the injectable fluphenazines—a conclusion that we consider yet to be established. Secondly, all patients had previous exposure to antipsychotic medication. The occurrence of EPS might be more frequent in patients without previous exposure.

One half of our patients were receiving concomitant oral antipsychotic medication. One might expect that this would increase the likelihood of developing EPS; however, Chien and Cole (12) report a lower incidence of EPS in patients receiving chlorpromazine and fluphenazine enanthate (33.3%) than in patients receiving fluphenazine enanthate alone (52.6%), although it was not statistically significant.

The fact that we examined patients for only two weeks may have also contributed to our findings. However, Ayd (17) reported that 90% of EPS associated with injectable fluphenazine occur within the first week of starting treatment. Certain EPS, however, take longer to develop. Akinesia, a syndrome characterized by apathy, loss of spontaneity, and psychomotor retardation, was observed by Rifkin and associates (18) to occur after several months of treatment.

The trend for fluphenazine enanthate to produce EPS earlier than fluphenazine decanoate is consistent with the findings of Itil and associates (8), who used quantitative EEG investigations, that fluphenazine enanthate has its maximum effect during the first week of administration, whereas the maximum effect of fluphenazine decanoate is reached in the second week. In addition, EEG analysis indicates that the activity of fluphenazine decanoate is longer than that of fluphenazine enanthate, which is consistent with the clinical findings of Van Praag and Dols (11).

Severe Depersonalization Treated by Behavior Therapy

BY DEBBIE SOOKMAN, M.A., AND LESLIE SOLYOM, M.D.

The author reports the use of behavior therapy in the treatment of two cases of severe intractable depersonalization. Outcome criteria included full psychiatric assessment, patients' self-ratings, and psychometric test scores. Treatment by flooding was highly effective in one case, and associated obsessive symptoms and anticipatory anxiety were substantially decreased in the other. Behavioral techniques may prove especially helpful in cases in which anticipatory anxiety, phobic avoidance, and obsessive perseveration are exacerbating features.

DEPERSONALIZATION occurs when there is a change in any or in all of the four fundamental aspects of self-awareness (1): 1) activity—an awareness that I am the one who wills my activity; 2) unity—an awareness that at any given moment I am unity; 3) identity—an awareness that I have been the same person all the time, that my past experiences belong to me; and 4) separateness—an awareness of myself. The sine qua non of depersonalization is an awareness of internal and/or external (derealization) change experienced as strange or unreal with the simultaneous experience of the opposite, i.e., that no change has occurred. Insight is not lost.

Depersonalization is frequently reported as a secondary aspect of many psychiatric illnesses, the most common of which are depression (2, 3), phobic anxiety states (4, 5), obsessive neurosis (6), and schizophrenia. It may also be a feature of hysteria (7) and temporal lobe epilepsy (8). However, cases in which the syndrome dominates the clinical picture are relatively rare.

Most episodes of depersonalization are transient (9), may be precipitated by identifiable situations, or be accompanied by a particular feeling state, such as hostility, frustration, anxiety, etc., which may provoke the episode. The few articles available indicate that depersonalization is very resistant to treatment (9–12). Although a mild form of it may respond to supportive psychotherapy, this is rarely effective in severe cases (10). Predominant depersonalization tends not to benefit from the treatments to which the associated symptoms of anxiety and depression respond [illegible] does not respond to tranquilizers, [illegible] anticonvulsants (9), or phenothiazines [illegible] ECT may be helpful in cases with clear[illegible] depression (12), Roth (13), and Sargant [illegible] have reported that ECT may exacerbate [illegible] precipitate depersonalization. In severe [illegible] cases, frontal leucotomy has been advo[illegible]

To the best of our knowledge, this pa[illegible] the first reported use of behavior therap[illegible] ment of two cases of severe depersonal[illegible] patients were incapacitated by daily epis[illegible] depersonalization that had persisted for [illegible] and had shown progressive worsening [illegible] ous previous pharmacologic and psycho[illegible] terventions (which in one case included [illegible] apy techniques of desensitization and fl[illegible]

Both patients were assessed on the fo[illegible] sures: 1) an open-ended psychiatric ques[illegible] ing all symptoms on a 0- to 4-point scal[illegible] tom complex consisted of four to six [illegible] mean of which provided the symptom [illegible] patients' self-assessment on a 0- to 4-[illegible] their depersonalization, obsessive-com[illegible] toms, other neurotic symptoms, and soc[illegible] ment; and 3) psychometric test scores [illegible] Obsessive Inventory (15), Fear Surv[illegible] IPAT Anxiety Scale Questionnaire, a[illegible] Personality Inventory.

CASE REPORTS

Case 1. Ms. A, a 48-year-old housewife, [illegible] treatment after 4 years of psychotherapy, gre[illegible] tranquilizing and antidepressant medicatio[illegible] produce any change in her constantly worse[illegible] depersonalization. She complained of feeli[illegible] ity" about herself and the world, which o[illegible] times daily and lasted from a few minutes t[illegible] with no identifiable triggering stimulus; se[illegible] and moderate social phobia; pervading doub[illegible] her incapable of making any decision; obsess[illegible] about trivia, and clinically unimportant ritual[illegible] ing to check her curtains, stove, door, etc. [illegible] dominantly, a depressive mood characteriz[illegible] of interest, feelings of worthlessness, insom[illegible] trate, diurnal fluctuations, and guilt (specific[illegible] ill).

The episodes of depersonalization had been [illegible] years before therapy by a temporary famil[illegible] then, her condition progressively worsened. [illegible]

Ms. Sookman is Psychologist, Behavior Therapy Unit, Allan Memorial Institute, 1025 Pine Avenue West, Montreal, Que., Canada H3A 1A1, where Dr. Solyom was Senior Psychologist; he is now Associate Professor of Psychiatry, McGill University, Montreal, Canada.

0002-953X/78/0012-1543$0.40 © 1978 American Psychiatric Association

quent and intense attacks of depersonalization, derealization, and panic. During the attacks she experienced marked color, visual, and auditory distortions, desomatization, and autoscopy. On assessment she was incapacitated.

Flooding treatment in fantasy was carried out with the use of grossly exaggerated taped narratives of depersonalization episodes based on Ms. A's description of her anxiety-provoking thoughts and sensorial experiences during the attacks; her own words were used as much as possible. She received 2 1-hour treatment sessions per week for a period of 10 weeks in addition to 8 flooding sessions in imagination for her agoraphobia.

Her depersonalization was reduced by 83% on psychiatric ratings and by 67% on self-rating. During the 8th treatment session Ms. A reported that her depersonalization experience was no longer continuous and that each episode was less intense. By the 20th session, the grossly disturbing depersonalization had been almost completely eliminated. She described her experience now as a feeling of "being aware of myself" or "being removed from the situation," and she seldom felt panicky. She felt she had regained her self-control and no longer avoided shops, buses, etc.

On psychiatric ratings, her phobias, particularly the agoraphobia, were reduced by 67%, her anxiety by 33%, and her depressive symptoms by 36%. There was also a substantial decrease in her ruminations (66.7%), horrific temptations (56%), and doubt (57.1%). Her rituals, originally subclinical, increased slightly.

On self-rating, there was also a substantial decrease in her obsessive-phobic and other neurotic symptoms (54.5% and 69.9%, respectively) and a substantial improvement in her social maladjustment (83.3%), especially in the areas of work, extra-familial activities, and expressed self-satisfaction.

At 1-year follow-up, her improvement was maintained. She occasionally experienced a feeling of self-awareness but without panic. She again became depressed but an exacerbation of the depersonalization experiences did not occur. Phenelzine, 45 mg/day for 5 weeks, terminated this depressive episode.

Case 2. Mr. B, a 40-year-old insurance salesman, was admitted to the hospital in a desperate, agitated state with feelings of unreality lasting from a few seconds to several weeks, the shorter episodes occurring up to 10 times a day. During these episodes, things felt unreal or dreamlike, with frequent time distortions, occasional visual and olfactory distortions and déjà vu experiences. He had obsessive ruminations and doubt surrounding his own state of awareness and intense fears of "going into unreality." He maintained a tortuous self-scrutiny in an effort to "keep myself in a state of awareness." Especially intense were his fears of darkness and all dark objects, including his own closed eyes, which he associated with feeling unreal. There was a daily increase in the number of such feared stimuli. Mr. B had an elaborate and incapacitating system of rituals to "get out of unreality" or as a preventive measure to "stay in reality." In order to undo a time distortion, for example, he would wait until the same time on the following day and recreate the situation right down to the same underwear and tie in order to repeat ritualistically and with absolute awareness the previous day's event in a nondepersonalized state. He was terrified of performing the most basic activities—showering, changing his clothes, brushing his teeth, etc.—and on admission was unable to do so.

Other less disturbing obsessive symptoms included a host of horrific temptations, obsessive fears, and all-pervading doubt and indecision. However, Mr. B showed no depressive features and no phobias other than the fear of darkness. One unusual feature was that when he was not depersonalized or ritualistic, he showed an unusually gregarious, friendly, and easy-going personality with very few obsessive personality traits.

Over a 2½-month period, 5 1-hour treatment sessions per week and several prolonged (2- to 3-hour) flooding treatments were given. During the flooding treatment, carried out mostly in vivo, Mr. B was exposed to the situations that provoked his depersonalization experiences, encompassing a large number of stimuli in random patterns to prevent habituation. Some paradoxical intention was employed when he was encouraged to say his dreaded "obscene" thoughts aloud or to try to induce a depersonalization episode.

Mr. B was strongly urged never to perform a ritual to terminate his feelings of depersonalization. In view of the nature of his rituals, self-monitoring was instituted to encourage complete response prevention, since 24-hour supervision was not possible. For his many ruminations a thought-stopping technique—a portable finger-shock apparatus—was used, first administered by the therapist and then by Mr. B during actual depersonalization episodes.

Within the first week of therapy, Mr. B began to extend his activities to include those situations to which he had been exposed during therapy. The flooding treatment seemed to have had very little therapeutic effect on the depersonalization. It was our impression that the episodes were reduced somewhat in frequency and in intensity, but Mr. B did not agree. However, the associated rituals were reduced by 63%. He reported feeling fewer urges to perform his rituals following a depersonalization episode, and the rituals he did perform (e.g., blinking) lasted a few seconds instead of hours. His avoidance behavior was markedly reduced. There was also a 50% reduction in his horrific temptations but only a 25% improvement in his ruminations and pervading doubt. Of greatest importance on the Leyton Obsessive Inventory was a 55% reduction in the interference score. Although the number of obsessive symptoms was only moderately reduced by treatment, their duration and intensity were reduced such that they interfered only half as much as previously.

Mr. B also considered his obsessive and other neurotic symptoms, such as anxiety, to be reduced by over 50%. He rated himself as substantially improved (63%) in all areas of work, leisure, and sexual performance. On returning home, Mr. B was able to resume his work, and at 6-month follow-up he had maintained his progress.

DISCUSSION

Two patients with a main complaint of depersonalization were treated with behavior therapy: In both patients, the depersonalization syndrome was long-standing and highly distressing and previously had shown no response to psychotherapeutic and pharmacologic intervention. However, the personalities of the patients and the other associated symptoms were quite different. In the first patient (Ms. A), depersonalization was connected with severe agoraphobia and mild obsessive symptoms and was not stimulus bound. Ms. A had high anxiety, high neuroticism, and low extraversion scores. This symptom constellation is simi-

lar to Roth's phobic anxiety depersonalization syndrome both in type of symptoms and in personality attributes. In the second case (Mr. B), the depersonalization ruminations, provoked by an almost infinite number of stimuli, led to obsessive rituals. The anxiety, phobia, and neuroticism scores were relatively low; the extraversion score was high. This is a case of long-standing severe obsessive neurosis with atypical personality characteristics. Thus, of the most common psychiatric conditions in which depersonalization is a clinically important feature—phobias, depression, obsessions, and schizophrenia—all but schizophrenia are represented.

The different outcomes of treatment—improvement in depersonalization versus improvement in rituals—may have been due to differences in the treated symptoms as well as to the different personalities and total symptoms of the patients. Flooding in imagination (case 1) proved to be more efficacious than flooding in vivo (case 2) in ameliorating the intensity and severity of the depersonalization episode. The salient factor may be that depersonalization is itself an experience of the imagination and is therefore more effectively treated in imagination.

Despite residual disabilities, both patients were satisfied with the results of treatment. Nevertheless, there remain some reservations about long-term results, as both patients still manifested fairly high posttreatment anxiety scores that may make them vulnerable to relapse.

Follow-up and further clinical application are needed to elucidate the indication for and long-term benefit to be derived from the use of behavior therapy in the treatment of depersonalization. Behavioral techniques may prove to be especially helpful in cases in which anticipatory anxiety, phobic avoid[illegible] sessive perseveration are exacerbating f[illegible]

Neurobiological Vulnerability to Low-Dose Amphetamine Psychosis

BY MARK S. GOLD, M.D., AND MALCOLM B. BOWERS, JR., M.D.

The authors present a case to illustrate a model of drug-induced psychosis wherein the drug acts as if it fits with some neurobiological predisposition in the patient. Patients with a good interpersonal developmental history but extreme sensitivity to a psychotomimetic drug may provide a model for neurobiological vulnerability to psychosis.

THE WELL-DOCUMENTED clinical similarity between amphetamine-induced and naturally occurring paranoid psychosis (1–7) has led to the proposition that amphetamine produces a model psychosis resembling paranoid schizophrenia in most respects. Support for this model psychosis has come from numerous studies that have been reviewed elsewhere (8–10). These studies have linked antipsychotic drug efficacy, amphetamine stereotypy, behavioral effects, and pharmacologically significant actions of amphetamine to alterations in dopaminergic activity.

Amphetamine psychosis has been produced in volunteer subjects by large cumulative doses of amphetamine (5, 6, 11). An amphetamine psychosis produced by cumulative administration of amphetamine is not a toxic psychosis in the usual sense. However, in another respect this syndrome is "toxic" in that it is limited by the presence of the drug in the body. At very low doses, amphetamine-like compounds can produce psychotic states resembling naturally occurring paranoid psychosis (1). The "low-dose" or amphetamine-precipitated psychosis may continue after the drug effect has dissipated (12–15). It is this low-dose or drug-precipitated reaction that we believe may be more relevant as a model of clinical psychopathology, i.e., a lock-and-key model wherein the drug acts as if it "fits" with some predisposition in the patient. Furthermore, in this low-dose model neither the drug nor the individual contribution is overriding. Both the drug and the individual vulnerability are required.

The model we are using is a component model of psychopathology. With regard to psychotic states, the primary components of this model are vulnerability to the psychotic state and the interpersonal developmental level of the individual. The question of drug-induced models of psychosis may be best scrutinized with this component model in mind. Such a model would predict that vulnerability to psychotic states and interpersonal developmental deficit are separable aspects of psychotic illnesses. It might be possible to isolate this vulnerability, which is unmasked by the provocative drug stimulus, in an individual who has a good interpersonal developmental history but is sensitive to a psychotomimetic drug. In this model the patient carrying such a vulnerability might not develop a prolonged psychosis without the administration of the drug.

To illustrate we will describe a patient with an exquisite sensitivity to amphetamine-precipitated psychosis in conjunction with a history of good interpersonal development. The case is presented as an example of the low-dose psychotomimetic phenomenon and an approach for studying the neurobiology of vulnerability to psychosis as a component of psychotic states.

CASE REPORT

Ms. A, a single 20-year-old woman, was living alone in an apartment at considerable distance from her parents. All of her brothers and sisters had moved out of the home after completing high school, continued their educational or vocational training, and eventually married and had children. Ms. A was the youngest of the four siblings. She was admitted to the Yale-New Haven Hospital Emergency Room and was referred to the clinical research unit with a diagnosis of amphetamine psychosis or schizophrenia. (Urine and blood toxicology tests at the time of admission were subsequently found to be negative.) Neither she nor any member of her family had any previous psychiatric contact, medication, or hospitalization. Three weeks before admission, Ms. A had planned a long drive for a ski weekend. After "a long day at work" she was tired and "borrowed" five 5-mg dextroamphetamine (Dexedrine) tablets from a friend who was under treatment for narcolepsy. She took 5 mg at the beginning of her drive, another 10 mg 3 hours later, and then another 10 mg at daybreak. No further amphetamine was ingested. She describes feeling hyperalert and vigilant throughout her drive but on arriving at the resort felt that she "had died and someone else was in my place." She described intense anxiety, suspiciousness, ideas of reference, hyperactivity, and dysphoria. She was so uncomfortable that she cut her vacation short and returned home. She went to work that next

At the time this work was done, Dr. Gold was a Behavioral Sciences Training Program Fellow, Yale University School of Medicine, Neurobehavioral Laboratory and the Department of Psychiatry, New Haven, Conn., where Dr. Bowers is Professor of Psychiatry. Dr. Gold is now Director of Research and Training, Fair Oaks Hospital, 19 Prospect St., Summit, N.J. 07901.

0002-953X/78/0012-1546$0.40 © 1978 American Psychiatric Association

Monday but felt that the "F.B.I. had agents watching me." She withdrew from her friends and family, feeling that they were imposters, and spent hours in a noncommunicative state. She demanded that her mother prove her "true" identity and accused her of being an F.B.I. agent. When her mother removed her false teeth as proof, Ms. A concluded that her mother was "a very good imposter but not my mother" (Capgras phenomenon). She began having auditory hallucinations and felt that she was Patty Hearst. She pleaded with her family not to "throw me in the closet." She had vivid dreamlike visual hallucinations, and her family described her as "hyper and always picking at her clothes." She tried to stay at home, but it became impossible when "I felt convinced that the apartment was bugged." She went to live with a sibling who, upon learning of the "drug abuse" and observing bizarre stereotyped behavior, increasing social withdrawal, and communication that at times was incoherent, brought her to the Yale-New Haven Emergency Room for treatment. Her interpersonal developmental level appeared good, and she had a record of age-appropriate adaptive behavior in her sexual adjustment, work, social adjustment, childhood development, and school performance. Interviews with her family members, teachers, employers, and friends failed to document pathological premorbid traits or behaviors. Medical and neurological evaluation was normal on admission.

Evaluation of this patient included measurement of probenecid-induced accumulation of the cerebrospinal fluid serotonin and dopamine metabolites, 5-hydroxyindoleacetic acid (5-HIAA) and homovanillic acid (HVA), respectively, as described by several investigators (16, 17), and serum prolactin, an accessible marker of tuberoinfundibular dopaminergic activity (18). We were looking for evidence of central dopaminergic overactivity in Ms. A before she began pharmacological treatment. During the second week in the hospital (when symptoms were minimal) values for 5-HIAA, HVA, and probenecid were 130 ng/ml, 145 ng/ml, and 17 μg/ml, respectively. During a subsequent drug-free, essentially asymptomatic period serum prolactin was 18 ng/ml. During treatment with chlorpromazine (500 mg/day, dose achieved after 21 days), CSF values for 5-HIAA, HVA, and probenecid were 67 ng/ml, 274 ng/ml, and 25 μb/ml, respectively. Medication was later changed to thiothixene (10 mg/day) at which time serum prolactin was 38 ng/ml.

Ms. A's motor stereotypies, hallucinations, and delusional thinking cleared in sequence. Visual and auditory hallucinations abated 8 days after admission and were followed by a marked decrease in delusional content over the next 72 hours. As she improved, Ms. A began to attend a discharge group and to take passes outside the hospital. After taking a number of these passes and seemingly doing well, Ms. A became quite disorganized and manifested a number of the symptoms seen on her admission. Urine and serum toxicology was repeated and again found to be normal. The EEG was abnormal, with prominent left temporal runs of sharp and spike activity. The EEG became normal on clinical remission 10 days later. After discharge, Ms. A returned to her level of premorbid functioning and was asymptomatic at 1-year follow-up.

DISCUSSION

Cases of psychosis following ingestion of low doses of amphetamine can be found in the literature dating back to the original description of amph[illegible] chosis by Young and Scoville (19). These [illegible] sented a case of paranoid psychosis that [illegible] over 1 year and led them to wonder abo[illegible] innate vulnerability in such a drug reactio[illegible] anecdotal reports suggest that even a [illegible] venous administration of amphetamine-l[illegible] can rapidly provoke or intensify psycho[illegible] in so-called "psychotic" or "borderline" [illegible] occasionally in "normal" individuals. M[illegible] experimental studies suggest that small [illegible] phetamine can temporarily intensify psy[illegible] tomatology in schizophrenic patients (7[illegible] nately, too often amphetamine psycho[illegible] conceptualized as being associated with [illegible] use of amphetamine and clearing within [illegible] after the urine no longer contained ar[illegible] those whose symptoms continued wer[illegible] have probable or latent schizophrenia [illegible] this post hoc argument is the belief [illegible] schizophrenic state can be characterize[illegible] nized in some reproducible way. F[illegible] sistence of psychotic symptoms in drug-[illegible] chotic states has not been found to correl[illegible] premorbid function, symptomatology or [illegible] history, or outcome (15, 17).

Vulnerability to prolonged psychotic s[illegible] by low doses of psychotomimetic drugs [illegible] sarily correlated with the level of interper[illegible] opment. Ms. A had premorbid characteris[illegible] from those usually reported for patients w[illegible] a remitting paranoid state or psychosis s[illegible] cumulative doses of amphetamine (5) an[illegible] regularly reported in schizotypic individ[illegible] tion to being precipitated by a low dose [illegible] mine, Ms. A's symptoms persisted fa[illegible] riod of acute drug effect. This amphetam[illegible] in conjunction with good premorbid fun[illegible] gests a neurochemical vulnerability tha[illegible] compensated for but that can be overrid[illegible] ence of catecholaminergic agonists like a[illegible] In this patient the vulnerability to psych[illegible] associated with premorbid "trait" deficits.

In this case of exquisite vulnerability [illegible] mine-induced psychosis, the question tha[illegible] the nature of such sensitivity. As opposed [illegible] dose psychotomimetic reaction in which [illegible] put is dominant, we must ask what pat[illegible] variables led to this low-dose, prolonged [illegible] amphetamine. Pharmacological data [illegible] phetamine and potent antipsychotic me[illegible] dopaminergic systems and literature on am[illegible] exacerbated psychoses support the role o[illegible] gic hyperactivity or supersensitivity in the [illegible] sis of some paranoid psychoses (9, 10). [illegible] response to a low dose of amphetamine [illegible] sisted for more than 1 month after withd[illegible] precipitating agent, could be compatible [illegible] mine hypothesis. One might postulate tha[illegible] ence of an amphetamine challenge the "[illegible]

nerability might allow for the development of persistent central dopaminergic overactivity and a paranoid state.

Our biochemical measures do not provide definitive information on these points. The CSF HVA value obtained when Ms. A was minimally symptomatic and unmedicated was certainly not elevated (17). The serum prolactin level measured at another asymptomatic, drug-free period was not low. These findings indicate that there was no generalized process at work in this individual which led to increased transmission in the nigrostriatal system (HVA) and/or increased dopaminergic inhibitory pressure on prolactin secretion. That both these systems are functionally intact is demonstrated by the expected responses to antipsychotic drugs in both systems, i.e., an increase in CSF HVA and serum prolactin. It is conceivable that other central dopaminergic systems (possibly limbic) currently inaccessible to direct clinical assessment may contain sites uniquely vulnerable to amphetamine. In this regard, the EEG findings in our patient are interesting. Stevens (21) has reviewed the evidence for the limbic system's involvement in the anatomy of psychosis. It is conceivable that the temporal spike activity in this instance is a reflection of limbic irritability relevant to amphetamine sensitivity and vulnerability to psychosis. Further investigations of patients with a good interpersonal developmental history but extreme sensitivity to psychotomimetic drugs are necessary to determine whether they provide a model for assessing the predictions of the dopamine hypothesis and dissecting out vulnerability to psychosis.

Enuresis Treatment with Imipramine Hydrochloride: A 10-Y Follow-Up Study

BY PAUL M. BINDELGLAS, M.D., AND GEORGE DEE, PH.D.

The authors followed 29 young adults who had been treated for enuresis with imipramine hydrochloride 10 years earlier. To test beliefs that enuresis is symptomatic of severe psychopathology or of urological conditions, they studied whether the treatment had been followed by psychological decompensation; an inhibition of learning; a predisposition to drug abuse; negative effects on health, growth, weight, and development; or continued urinary symptoms. None of these negative effects was present; in general the subjects were active, well-motivated, and sociable and showed no significant psychiatric symptoms. One patient still wetted but only occasionally.

THERE IS considerable controversy about the use of medication for treating children, particularly when it is for the treatment of enuresis. Fear has been expressed that the long-term effects of medication for enuretic children would lead to 1) psychological decompensation, 2) inhibition of learning, 3) predisposition to abuse drugs as the child grows older, and 4) deleterious effects on health, growth, weight, and development.

Some believe that wetting is a symptom of severe psychopathology in the child and the family and that the removal of this symptom leaves the pathology intact and may result in further psychological decompensation and more severe symptomatology (1).

After reviewing reports by MacLean (2) and others (3) on the positive results of imipramine hydrochloride in the treatment of enuresis, we began a controlled study of its effects on enuretic children whose parents responded to a newspaper article about the study (4). Response to the medication was generally favorable, and a 2-year follow-up indicated that the fears of symptom removal were groundless [illegible] (5). However, the children were still [illegible] to evaluate the long-term effects on [illegible] adults, so 10 years after the start of [illegible] tempted to contact 44 of the children [illegible] pleted our original study to evaluate [illegible] fects of imipramine hydrochloride [illegible] dren.

Revised version of a paper presented at the 130th annual meeting of the American Psychiatric Association, Toronto, Ont., Canada, May 2-6, 1977.

The authors wish to thank Geigy Pharmaceuticals for contributing data about their original study and for supplying technical help and the entire staff of the Jane Wayland Child Center for assistance in this study.

METHOD

We developed a telephone contac [illegible] about the subject's adjustment to sc [illegible] and family; drug, tobacco, or alcoho [illegible] traits; illnesses or accidents; and he [illegible] history of bedwetting. The original fa [illegible] subject were available from the earli [illegible] cluded the subjects' addresses, [illegible] schools, the age at which bedwetting st [illegible] of night that the wetting occurred, th [illegible] bedwetting, the degree of bedwetting [illegible] the family who were bedwetters, the [illegible] of bedwetting, and the child's heigh [illegible] patients' responses to the treatmen [illegible] study were also available.

Due to the long time that had elapse [illegible] tion of the population, only 29 famil [illegible] tacted. Subjects were found throug [illegible] States; 2 were overseas. Patients' ag [illegible] to 25 years (mean, 19 years).

A psychiatrist (P.M.B.) interview [illegible] completed the Hamilton Depression R [illegible] for each of them. A psychologist (G. [illegible] ject's height and weight, administered [illegible] BM from the Thematic Apperceptio [illegible] and the patient completed the Zung Se [illegible] for Depression (8). An additional con [illegible] with 17 families 6 to 8 months after th [illegible] view to check on the constancy of res[illegible]

RESULTS

To measure possible psychologica[illegible] tion, a comparison of emotional and [illegible] lems before and after the original stu[illegible] ing responses to questions asked in the [illegible] terview, the descriptive adjectives c[illegible]

0002-953X/78/0012-1549$0.45 © 1978 American Psychiatric Association

mother to describe the subject, and data from the original study.

The number of subjects who displayed psychological or emotional symptomatology of any significance was small. We subdivided patients into those who had problems before the study and those who had problems after the study. Eight subjects were reported to have had problems before the study. Four of them indicated they were having problems at the time of follow-up, as did 1 patient who had no reported emotional problems 10 years before. This subject was functioning adequately at home and at school, but his mother considered him "emotional."

In general, the subjects were active, well motivated, and sociable and showed no significant depressive symptomatology, anxiety, or other psychological-emotional problems.

The essential lack of psychological problems was confirmed by the sampling psychiatric and psychological interview that was given to 9 patients. Testing with the TAT pictures, the Hamilton scale, and the Zung Self-Rating Scale for Depression, and the impressions of the psychologist and psychiatrist indicated this same conclusion. An evaluation was completed on these 9 patients using the findings of the original and current studies, and there were no indications that psychological decompensation or more severe psychiatric symtomatology occurred with the removal of the symptoms of enuresis.

School and Work

Of the 29 subjects contacted, 15 were still in school; most of those who were out of school had finished high school and were working, and the few who had not finished high school were all working. The 2 patients who were not in school or working had completed high school the summer before contact. Many subjects were involved in various extracurricular activities in addition to their studies.

While in school, 10 subjects were in the upper third, 12 were in the middle third, and 7 were in the lower third of their class academically. We found no evidence to support the assumption of an inhibition in learning.

Substance Abuse

That using drugs as a child would lead to a predisposition to use drugs is based on the assumption that the subjects would abuse drugs, particularly pills, because of a psychological reliance. We distinguished marijuana use from other drug use and added the use of alcohol and tobacco. Marijuana use, which includes having tried it but not using it regularly, has been estimated to be 20% or higher locally for the age range studied (9).

We asked the subjects to rate their use of marijuana, other drugs, alcohol, and tobacco as "frequent," "some," or "never"; the "some" category covers those who have tried or used a substance occasionally but does not include regular users. Two individuals reported "some" use of marijuana; none reported using it frequently, and 27 said they had never tried it. Of the 2 who did use it, the use was extremely light. Ten of the 29 had used tobacco, but only 5 reported being frequent users. Thirteen reported using alcohol, but only 2 reported fairly frequent use. No family members or patients reported any other form of illicit drug use. As can be seen, this group had remarkably little contact with drugs.

Physical Growth and Development

The original study included data on height, weight, and physical health, and the follow-up also covered these areas. Using Public Health Service height-weight statistics (10) and tables developed by the Metropolitan Life Insurance Company (11), we rated each subject as above average, average, or below average for height and weight at the time of the original study and at follow-up.

The majority of subjects maintained their same growth position in regard to height and weight; 20 maintained their height status, and 23 maintained their relative weight. Six subjects had increased and 3 had decreased their relative height, and 5 had increased and 1 had decreased their relative weight. On the whole this was a fairly well-functioning, healthy group of young adults that was not being significantly hampered by any health problems. There is no evidence to support the assumption of a deleterious effect on health or growth development.

Consistency of Responses

In addition to the 9 subjects who were interviewed by a psychiatrist and psychologist, 17 families were recontacted after 6–8 months to check on the constancy of responses. The responses did not change, which supports the reliability of the telephone interviews.

Urological Symptoms

Arnold and Ginzberg (12, 13) and Mahoney and associates (14, 15) wrote about the high incidence of urogenital symptomatology in enuretic children. They felt that the treatment of choice for most of these children would be urological procedures and that if such procedures were not done, even though many of these children would eventually outgrow their enuresis, the other urinary symptoms such as urgency, frequency, and burning would persist. Therefore, we attempted to check out these contentions. We reviewed the original records of the 29 children in the follow-up; 12 subjects had other urinary symptoms such as frequency and urgency. Four of them had daytime wetting. During our follow-up we inquired as to whether there was any persistence of enuresis and urinary frequency or urgency.

Of the 29 patients, all but 1 reported that they no longer wetted and the 1 patient wetted only occasionally. This patient reported still having symptoms of frequency and urgency. The other 11 who had reported urinary symptoms in the original study were free of urinary symptoms at follow-up. One may speculate

that, just as a psychiatrist or mental health clinic treats many enuretic children with a high incidence of emotional pathology, a urologist may receive a high incidence of referrals with signs indicative of urinary pathology, with the result that both groups tend to get a distorted view of the etiological factors in enuresis.

The results of the 10-year follow-up study support the findings and observations we made at the end of 2 years (5). We again found imipramine hydrochloride to be safe and effective in the treatment of enuretic children. The mere removal of symptoms produced no psychological complications but, rather, had a healthy effect on the child and his or her family.

DISCUSSION

The prevailing view has been that enuresis is indicative of severe psychological and family problems, and, just as with hysteria, if one removes the symptom without treating the underlying cause there is the possibility that the patient will experience further psychological decompensation and even more severe psychopathology. However, most studies that have reported a high incidence of emotional problems in enuretic children have come from child guidance clinics, where one would normally expect to find a high incidence of psychopathology (16). In our original study, in which our patients came in response to a newspaper article about our investigation of the use of imipramine hydrochloride in enuresis, we did not find a high incidence of psychopathology.

Arnold and Ginzberg (12, 13) and Mahoney and associates (14, 15) reported finding many enuretic children who suffered urological conditions. (Arnold and Mahoney are both urologists.) Others have reported small bladder capacity (17), neurological problems (18), and allergic disorders (19, 20) that cause bladder irritability and contraction of bladder size. In addition, there are enuretic children who become enuretic following stressful events in their lives and there are many who are psychologically immature and have severe psychopathology. Thus, we believe that enuresis is a symptom, like a cough, which can have multiple and varied etiologies. We also believe that just because an enuretic child has concomitant emotional problems, one should not assume without further evidence that the enuresis is caused by the emotional problems. We have found that many enuretic children with severe concomitant psychopathology respond well to imipramine hydrochloride and show no evidence of psychological decompensation. In a few instances where for psychological reasons either the child or the family has an emotional need for the enuretic symptom to persist, treatment is discontinued or the child will start wetting again in spite of treatment.

We used the data from the original study (5) to compare and contrast changes, but we also asked the respondents for their memory of the original study. There was a discrepancy between our records and what the parents and the youngster remembered about the effects of the medication, but the discrepancy was greater for those who were contacted twice were closer [illegible] general, it would appear that only when the medication had an immediate and dramatic effect was there a tendency to remember that the medication had a positive effect. Thus, 3 mothers who had been told by the medication indicated that their children stopped wetting almost immediately and were parents of children who were on medication at the beginning of the double-blind part of the study. None of the parents of children who started on placebo had such a reason for the medication. Some parents formed their judgment on the basis of time sequence. When the cause and effect between the medication and the enuresis—wetting was slow and less dramatic, they tended to give the medication less credit and to assume the enuresis stopped because of other reasons.

In general, both parents and patients seemed to consider enuresis something to be ashamed of and often denied it. Thus, although cooperative, most parents made remarks that indicated they wanted to protect the patient from embarrassment at having been the enuretic child. In general, the patients themselves had very hazy recollections of being enuretic, having stopped, or of even having been in the study.

Sexual Function and Affect in Parkinsonian Men Treated with L-Dopa

BY EDWARD BROWN, M.D., GREGORY M. BROWN, M.D., PH.D., OSCAR KOFMAN, M.D., AND BRUCE QUARRINGTON, PH.D.

Using psychiatric interviews, sexual and affect rating scales, hormonal studies, and neurologic assessment, the authors assessed the effect of L-*dopa treatment on men with Parkinson's disease. Patients demonstrated variable affect changes. Approximately one-half of the patients reported an increased sexual interest that was not related to improvement in locomotor function. Hormonal factors appeared to be involved. The findings suggest that male parkinsonian patients who possess an intact hypothalamic-pituitary-gonadal axis experience increased sexual function related to* L-*dopa treatment.*

THE USE of L-dopa in the treatment of Parkinson's syndrome has been reported to correlate with alterations in affect (1-6) and sexual function (1-5, 7, 8). It remained to be determined if these alterations were related to drug effect or placebo response or were secondary to the reduction of locomotor impairment. In this study the effect of L-dopa therapy was assessed in men with Parkinson's disease by using psychiatric interviews, sexual and affect rating scales, hormonal studies, and neurologic assessment.

This study was supported in part by a grant from the Mount Sinai Hospital, Toronto, Ont., Canada, and by grant MT-4749 from the Medical Research Council of Canada.

METHOD

The subjects were 7 men with Parkinson's disease who ranged in age from 59 to 69 years (mean=62). They had been ill for 1-7 years (mean=4). All patients were receiving the standard antiparkinsonian medications, benztropine mesylate and trihexyphenidyl HCl, but they had not received L-dopa before this study. Their dosages of benztropine and trihexyphenidyl were unchanged throughout the study.

At the beginning of the study, each patient received a thorough physical examination as well as a psychiatric assessment. Neurologic status was assessed at intervals. Each patient was asked to complete self-administered sexual interest and affect questionnaires each day at the same time.

On the sexual interest rating scale, each patient was asked to give a single numerical response (1 to 9) that corresponded to a specific question reflecting drive-intensity (e.g., 1=no interest in sexual matters, 5=some things are of sexual interest, 9=readily excited sexually). In addition, each patient was asked to respond to questions about specific behaviors (e.g., masturbation, intercourse without ejaculation, intercourse with ejaculation); responses tended to confirm the validity of the sexual interest rating scale. On the affect rating scale, each patient was asked to give a single numerical response (1 to 9) that corresponded to a specific question reflecting affect (e.g., 1=extremely unhappy, 5=not happy or unhappy, 9=extremely happy). Patients were also asked to respond to questions regarding specific behaviors (e.g., feeling like crying, hopelessness, energy level, wanting to be alone); again, results tended to confirm the validity of the rating scale. Mean values were calculated for each patient on the various measures at each phase of the study (baseline, placebo, stable L-dopa dose). Findings were then subjected to analysis of variance.

 0002-953X/78/0012-1552$0.45 © 1978 American Psychiatric Association

Plasma luteinizing hormone (LH) and prolactin[1] were measured by radioimmunoassay with methods and materials supplied by the National Institute of Arthritis, Metabolism, and Digestive Diseases. Blood specimens were collected weekly in the early morning of the same day each week.

The following sequence was followed for each patient in a single-blind method: period 1 (baseline)—3 weeks in which no placebo or L-dopa was given; period 2 (placebo)—3 weeks in which placebo was given; and period 3 (L-dopa treatment)—a period of changing L-dopa dosage, followed by a period of stable L-dopa dosage (3–18 weeks).

RESULTS

Psychiatric Interviews

The psychiatric assessments were done before the baseline study period. Patient 2 failed to complete the psychiatric assessment but continued to participate in all other aspects of the study. Patient 3 exhibited moderate anxiety symptoms with some depression. Patients 5, 6, and 7 were moderately depressed. Patients 1 and 4 were within the normal range of affect.

The patients fell into three categories of sexual function. Patients 3 and 4 reported marked reduction in sexual desire and erectile and ejaculatory capability that preceded the onset of Parkinson's disease. Patients 1, 6, and 7 reported a marked reduction in sexual desire and erectile and ejaculatory capability that coincided with their parkinsonian symptoms. Patients 2 and 5 reported a satisfactory level of sexual desire and sexual potency, which did not change with the onset and progression of their symptoms.

Sexual Interest and Sexual Activity Ratings

Patient 1 had a significant increase in the sexual interest rating during the drug period ($p<.001$), but his masturbation frequency showed a nonsignificant decrease during this period. His frequency of intercourse showed little change.

Patient 2 showed a significant increase in sexual interest ($p<.001$) during the placebo period but not during L-dopa administration. However, his intercourse frequency decreased during the placebo period and rose markedly ($p<.004$) with L-dopa.

Patient 3 showed a decrease in sexual interest ($p<.001$) during the L-dopa period. This patient developed side effects that necessitated a number of dosage changes. He reported no sexual activity throughout the study.

Patient 4 showed a progressive decrease in sexual interest throughout the study ($p<.001$) and reported no sexual activity.

Patient 5 showed little change in sexual interest. He reported no masturbatory activity until he began to receive L-dopa. The Fisher exact test comp[illegible] batory frequency in the placebo pe[illegible] stable drug dosage period showed no [illegible] ference. This was probably due to the fa[illegible] cebo period was only 20 days long. W[illegible] and placebo period combined were c[illegible] period of stable drug dosage, the diffe[illegible] cant ($p<.01$).

Patient 6 showed a marked increase [illegible] ual interest through the placebo perio[illegible] period. This increase could not be [illegible] drug alone since it appeared during th[illegible]

Patient 7 showed no changes in any [illegible] throughout the study.

Thus, 2 patients showed evidence [illegible] ual functioning that was probably rel[illegible] patients showed increased sexual in[illegible] be attributed in part to the drug but in [illegible] tors as well, 2 showed reduced sexu[illegible] showed no change. In patient 3, [illegible] seemed to be related to L-dopa, pro[illegible] verse side effects. The reduced sexua[illegible] ed by patient 4 was part of a trend thr[illegible] od in which he was studied. Factor[illegible] drug were operating, perhaps as part [illegible] thexis related to the subject's chronic [illegible] to which he succumbed a few month[illegible] period.

Affect Ratings

Mean values for affect for each of t[illegible] periods were determined for each pati[illegible] termined the mean values (±1.5 SD) f[illegible] control subjects (men aged 57–67 in good [illegible] with no psychiatric history).

Patient 2 showed a baseline affect s[illegible] mal limits. During the placebo period, th[illegible] nificant increase in his affect ratings th[illegible] tained during the period of stable dr[illegible] patient therefore appeared to have a [illegible] sponse to placebo.

Patients 3, 5, and 6 showed baseli[illegible] ratings at or below the control va[illegible] showed no significant changes with [illegible] Patient 5 improved significantly to ne[illegible] ing L-dopa administration. Patient 6 sho[illegible] cant level of improvement with placeb[illegible]

Patients 1, 4, and 7 showed no sig[illegible] over the three periods and all values w[illegible] mal limits.

Statistical analysis (Pearson correlat[illegible] of data for all patients as a group duri[illegible] L-dopa treatment indicated a significan[illegible] tive correlation between affect a[illegible] ($r=.1716$, $p<.002$).

Pearson correlation coefficients bet[illegible] terest and affect scores were calculate[illegible] a group for the combined baseline and [illegible] ods, the period of L-dopa treatment, and [illegible] ods combined. Sexual interest was sign[illegible]

[1]Data were insufficient for analysis of prolactin changes.

to the affect score only for the combined study periods ($r=.73$, $p<.001$).

The data suggest that affective state did not play a consistent role in determining sexual interest, particularly in subject 1, who showed an increase in sexual interest without a corresponding change in affect.

Neurologic Findings

Patient 1 had tremor with very mild rigidity that improved with treatment. With the exception of minimal residual tremor, his pattern returned to a relatively normal state.

Patient 2 had significant tremor in the right arm with very slight rigidity. With L-dopa treatment the tremor improved somewhat but did not cease. There was no alteration in the mild rigidity.

Patient 3 initially had mild to moderate bradykinesia with very slight tremor and mild rigidity. The bradykinesia improved somewhat but was still present. The rigidity and tremor were unchanged.

Patient 4, who had bradykinesia, tremor, and moderate rigidity, showed little essential change with L-dopa treatment.

Patient 5 had mild bradykinesia, significant tremor in the left arm, and a very slight tremor in the right arm. There was mild rigidity in the left arm. Following treatment there was considerable improvement in the tremor, with mild residual tremor in the left arm only. The bradykinesia improved substantially.

Patient 6 had moderate bradykinesia and moderate tremor, particularly in the left arm and leg. The severity of these symptoms was mild after treatment.

Patient 7 had pronounced tremor and mild rigidity in the left arm, slight tremor in the right arm, and mild bradykinesia. With treatment the bradykinesia disappeared; tremor and ridigity persisted but were less pronounced.

The data did not permit intraindividual statistical analysis. However, there were sufficient data to perform statistical analysis for patients as a group for baseline-placebo versus L-dopa periods. There were no positive correlations between neurologic parameters and the ratings for sexual interest or for affect. This would suggest that the alterations in sexual interest and affect in parkinsonian patients treated with L-dopa are independent of changes in neurologic function.

Luteinizing Hormone

There were significant changes ($p<.05$, analysis of variance) in LH in patients 2, 5, and 6. Patient 5 had no significant baseline-to-placebo change but showed a significant increase during L-dopa treatment. Patient 2 demonstrated an increase during placebo but only a slight further increase with L-dopa, indicating the involvement of factors other than L-dopa treatment. Patient 6 showed a significant drop in LH from baseline to placebo and from baseline to L-dopa treatment. The 4 other patients showed no significant changes in plasma LH throughout the study. These findings suggest that factors other than L-dopa influenced plasma LH. Patients 2 and 5, who showed significant increases in sexual activity with L-dopa treatment, also showed significant increases in plasma LH.

DISCUSSION

In this study, 4 of 7 men with parkinsonism reported increased sexual interest or sexual activity related to treatment with L-dopa. (One of these men also reported increased sexual interest with placebo.) In other studies (1–3), in which patients were not specifically questioned about their sexual function, the incidence of increased sexual interest or activity was consistently low—about 4%. In studies wherein the patients were questioned (4, 7, 8) approximately 30% reported increased sexual interest or activity with L-dopa treatment. Further review of these studies revealed that three times as many men as women with parkinsonism reported increased sexual function with L-dopa. Recalculation of rates from other studies for men only, taken together with our own findings, would indicate that the incidence of increased sexual interest or activity among male parkinsonian patients receiving L-dopa is approximately 50%.

It has been suggested (9) that L-dopa may act via the hypothalamic-pituitary-gonadal axis to induce a hormonally related increase in sexual function. The majority of female parkinsonian patients reported in the literature were probably postmenopausal and therefore were less likely to possess an intact hypothalamic-pituitary-ovarian axis. The findings in the present study are compatible with this hypothesis. Those patients with the longest history of impotence showed no increase in sexual function with L-dopa. Those who had no history of impotence (patients 2 and 5) and were more likely to have an intact hypothalamic-pituitary-gonadal axis showed an increase in sexual activity with L-dopa. Moreover, it was the latter patients who also showed an increase in LH with L-dopa. Intrapsychic and interpersonal factors such as the fear of failure in reestablishing sexual behavior after prolonged abstinence must also be considered.

Our neurologic findings are in agreement with those of Bowers and associates (8), who found no significant correlation between sex drive and improved locomotor function in parkinsonian patients treated with L-dopa.

Three of the patients in this study showed evidence of moderate depression before treatment. This is consistent with the findings in other studies (4, 10), in which approximately 50% of patients with Parkinson's syndrome were found to be depressed.

In studies involving parkinsonian patients receiving L-dopa, the affect responses have varied. Jenkins and associates (3) reported that 14 of 90 patients receiving L-dopa became depressed. Marsh and Markham (11) reported no change in Minnesota Multiphasic Personality Inventory depression scores with L-dopa, al-

though there was significant improvement in locomotor functioning. Other studies (1, 3-6) have reported an apparent hypomanic response to L-dopa.

This variable affective response to L-dopa has been observed in studies involving nonparkinsonian patients. Goodwin and associates (12) reported that only patients with retarded depressions improved with L-dopa (administered with a peripheral decarboxylase inhibitor); most of the endogenously depressed patients had no change or became worse. Murphy and associates (13) found that 8 out of 9 nonparkinsonian bipolar depressed patients in their study developed a hypomanic response to L-dopa. Only 1 of 12 unipolar depressed patients manifested a hypomanic response to L-dopa.

This variable affective response to L-dopa was demonstrated in the present study. Only two of the three moderately depressed patients showed an improvement in affect related to L-dopa. One patient (patient 2) demonstrated a hypomanic response to placebo.

CONCLUSIONS

Our study and the review of other findings have indicated that there is a high incidence of sexual impotence and depression in male patients with Parkinson's disease. With L-dopa treatment, parkinsonian patients demonstrated variable affective changes. Two patients with a history of reduced sexual function reported an increase in sexual interest with L-dopa treatment (one also reported increased interest with placebo) but did not report any change in sexual activity. Two patients with no history of impaired sexual function reported an increase in sexual activity with L-dopa treatment. The improvement in sexual function for the group as a whole was not related to improvement in locomotor function. Hormonal factors did appear to be involved in the L-dopa-related increase in sexual activity. These findings suggest that parkinsonian patients who have not undergone an interruption of sexual activity and who possess an intact hypothalamic-pituitary-gonadal axis may undergo an increase in sexual activity relative to L-dopa treatment.

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Computerized Tomography and Skull X Rays: Relative Efficacy in Detecting Intracranial Disease

BY LUKE TSAI, M.D., AND MING T. TSUANG, M.D., PH.D.

Computerized tomography (CT) is an important new noninvasive neuroradiologic method for detecting intracranial disease (1). It provides as much information about intracranial structures as any other single investigative procedure currently available. However, many hospitals still routinely take skull X rays in addition to using CT scan when organic brain syndrome is suspected. The purpose of the present study is to evaluate whether routine use of both procedures is justified.

Subjects and Method

One hundred and twenty-five patients admitted to the inpatient unit of the Iowa Psychiatric Hospital from 1973 to 1976 received both CT scans and plain skull X rays in addition to initial neurologic and psychiatric evaluation. The age of these patients ranged from 5 to 82 years, with mean ages of 44 for women (N=62) and 35 for men (N=63). The reasons for CT and X ray referral included evidence of memory deficit or deterioration of intellectual function on clinical and/or psychometric testing, persistent or unexplained confusional state, focal abnormality or neurologic examination suggestive of intracranial pathology, focal or generalized seizures, focal or generalized EEG abnormality, evidence of mental retardation, history of poorly explained rage attacks or aggressive behavior, and unusual headache history. The CT scans were performed and interpreted by the department of radiology of the same medical center. We compared the results of the skull films with the CT findings to determine the efficacy of these diagnostic procedures.

Results

Table 1 shows the results of this comparison between skull film and CT scan findings for the 125 patients. In 6 of the 125 patients both CT scans and skull films were positive. In 1 of these patients the skull film showed a shift of the pineal to the right. This diagnosis was confirmed by CT, which showed enlargement of the ventricles. In another case the skull X ray detected intracranial calcification caused by tuberous sclerosis, while CT detected not only the calcification but also the precise location of the lesions. In a patient with a history of a gunshot wound to the head, both skull film and CT located the shotgun pellets. Another patient's skull film indicated Paget's disease and acromegaly, while CT detected cortical atrophy combined with ventricular enlargement. In 2 patients the skull films showed only calcification around the sella turcica, whereas both CT and EEG demonstrated that the cerebral atrophy was a contributory cause of organic brain syndrome.

Of the 29 patients with positive CT scan and negative skull X rays, 12 had cortical atrophy, 4 abnormal ventricular size, 8 cortical atrophy with ventricular enlargement, 4 cerebral infarction, and 1 demyelinating disease.

Five patients had positive skull X rays that indicated possible intracranial tumors, but CT scans were normal. The skull film of 1 of the patients, a 44-year-old woman, showed meningioma. A 21-year-old woman's film showed upward shift of the pineal, and that of a 29-year-old man demonstrated thinning of the dorsum sella. Another patient, a 23-year-old woman, showed

TABLE 1
Results of Comparison of CT Scan and Skull Films in 125 Patients

Outcome Combinations	Number	Percent
Abnormal CT/abnormal X ray	6	4.8
Abnormal CT/normal X ray	29	23.2
Normal CT/abnormal X ray	5	4.0
Normal CT/normal X ray	85	68.0

increased density of the sphenoid on the skull film. The last of these patients, a 16-year-old girl, had questionable increased intracranial pressure. Radionuclide scans and EEGs done on these 5 patients were normal except that the 23-year-old woman showed a left-right shift of slow waves over the temporal region on her EEG. However, this EEG finding is not compatible with intracranial tumor.

Discussion

The CT scan measures small differences in tissue absorption of X rays, permitting the identification of normal and abnormal structures of the brain, ventricles, and subarachnoid space. These changes in density also make it possible to detect brain edema and hemorrhage and to distinguish them from cerebrospinal fluid, as well as determining ventricular size or displacement. Mori and associates (2) found no false positives when they compared the detectability of lesions by good CT scans with lesion size as measured pathologically. Current data suggest that CT has an overall accuracy rate of 90%–98% in the detection of abnormalities (3) compared with the skull X ray, which has perhaps the lowest yield (50%) of any of the neurodiagnostic methods (4).

CT has several unique advantages over skull films in the location and characterization of tumors that can lead to more accurate planning of complex treatment. CT is extraordinarily effective—100% accurate in several series (3)—in detecting intracranial hemorrhage (cerebral, cerebellar, intraventricular), whereas skull X rays are rarely helpful. One study reported 85% accuracy of CT scans in detecting vascular abnormalities larger than 1.5 cm, including arteriovenous malformation and aneurysm (5); skull films barely detect these abnormalities. CT identifies significant nonacute disease (i.e., cerebral atrophy, porencephaly, old infarction) and clearly defines both normal and abnormal ventricular size and configuration, things that skull X rays cannot do. Demyelinating diseases and changes in the infectious disorders of the brain are evident on CT, whereas skull films are rarely helpful in such cases.

In Delaney's review of 2,943 cases (6), skull films revealed some abnormalities in 17.3% of the patients and significant abnormalities in 2.4%. Seven patients had skull film diagnoses of enlarged sella turcica, but after pneumoencephalography and other medical investigation only 3 of them were considered for surgery. The skull films of 5 other patients with clinical signs of increased intracranial pressure, but subsequent tests did not reveal any neurologic abnormalities. The author concluded that the small yield of significant findings does not seem to justify the effort and expense of routine skull films (6). Bull and Zilkha reported that the great majority of skull films taken for conditions such as migraine or headache, parkinsonism, vertigo, Ménière's disease, and epilepsy, in the absence of clinical signs, did not contribute materially to the diagnosis (7). In the diagnosis of dementia, Bull and Zilkha concluded that skull films were wasteful and unrewarding.

In our study, skull films detected significant abnormalities (intracranial calcification and sella turcica changes) as contributory causes in 2 patients, but CT scans detected these findings. In addition, the skull X rays of 5 patients indicated possible brain tumors, but CT scans, radionuclide scans as well as EEG failed to support these findings. It is apparent that even when positive findings, skull films rarely contribute to the confirmation of intracranial pathology.

With the ever-increasing cost of health care, the goal of clinicians must be to maximize the use of simple diagnostic tests in order to use the fewest possible that are most likely to give the correct diagnosis with the least risk to the patient and the most cost-effective use of the patient's or third-party payer funds. CT results and those of other studies indicate the efficacy of skull X rays in detecting neuropathology is limited. Thus, the routine use of both skull X rays and CT scan is not justifiable in terms of patient benefit and increased cost.

Oral-Buccal Dyskinesia Symptoms Associated with Low-Dose Benzodiazepine Treatment

BY SEYMOUR R. KAPLAN, M.D., AND CHARLES MURKOFSKY, M.D.

This case report describes the temporal correlation between low-dose benzodiazepine treatment and the occurrence of oral-buccal dyskinesia similar to the oral symptoms associated with neuroleptic drug-induced tardive dyskinesia. We have been unable to find other reports in the literature describing oral-buccal dyskinesia associated with benzodiazepine treatment.

Case Reports

Mr. A, a 63-year-old man, was seen because of hypochondriacal complaints and depressive symptoms. His internist reported no physical findings other than a mild hypertensive condition, which was controlled by hydrochlorothiazide. The patient had a family history of psychiatric illness, and his son had suffered from tics in early adolescence.

Mr. A initially obtained relief from his depressive symptoms with amitriptyline, 150 mg/day. He subsequently was sustained on a dosage of 50 mg/day, except for intermittent exacerbations of the depressive affect that required resumption of the higher dosage. The patient's somatic anxieties and insomnia continued, although lessened in intensity. These symptoms were ameliorated by diazepam (15 mg/day) and flurazepam (30 mg/q.h.s.).

During an exacerbation of depressive symptoms that required the higher amitriptyline dose, Mr. A began to have rhythmic involuntary oral-buccal movements (1 per second) that were "fish-like"; i.e., he pursed his lips and made sucking motions and then protruded his tongue. There were no involuntary movements of the extremities, trunk, or neck.

Because Mr. A had no history of neuroleptic treatment and there have been reports of the association of imipramine with tardive dyskinesia (1, 2), amitriptyline was discontinued. However, the involuntary movements did not diminish.

Mr. A remained on diazepam and flurazepam in the same dosage for 13 months after amitriptyline was discontinued. Both drugs were then stopped, and the involuntary movements unexpectedly ceased within 72 hours.

Because of Mr. A's marked discomfort following the discontinuation of the benzodiazepines and the uncertainty about the specific relationship of diazepam and flurazepam to the involuntary oral-buccal movements, he was instructed to take one 5-mg tablet of diazepam that evening and two 5-mg tablets the next day. He was asked to call about his condition after he had taken the second dose. He reported that the involuntary movements had returned. The benzodiazepines were discontinued and the movements again stopped within 72 hours.

Amitriptyline (150 mg/day) was resumed the day his involuntary movements stopped, after a 1-year hiatus. There was no recurrence of the dyskinesia. Mr. A showed moderate improvement in his depressive symptoms within 8 days, when he had a pleasant and relaxed evening. However, he relapsed the next morning and made a serious suicidal attempt. He ingested at least 20 tablets of flurazepam (15 mg) and an unknown amount of codeine, chloral hydrate, and alcohol. The blood alcohol level on hospital admission was 0.5%. A respirator was required because of the effect of the drugs on the central nervous system.

Two days after his ingestion of flurazepam, there was a recurrence of the oral-buccal dyskinesia. The movements stopped 4 days later at which time Mr. A again complained of marked agitation and perspiration, severe muscle aches, and insomnia. On examination, he had a fine tremor of the hands and memory lapses for the day's events. In addition, he showed uncharacteristic fearfulness and ideas of reference. The symptoms were considered to be part of a drug-induced withdrawal reaction. A neurologic examination and an EEG conducted the next week showed no abnormalities.

Discussion

This case illustrates the temporal association of prolonged low-dose benzodiazepine treatment and the development of oral-buccal dyskinetic movements, similar to the symptoms of neuroleptic-induced tardive dyskinesia. This is the first known report of a possible causal relationship between benzodiazepine treatment and dyskinetic symptomatology. It must be balanced with the fact that benzodiazepines are the most widely prescribed drugs today, with 44,280,000 prescriptions during 1974–1975 (3).

There have been several reports in the recent literature describing dyskinetic symptoms associated with the use of drugs other than neuroleptics. In 1973, Crane observed that "a variety of drugs, including amphetamines and L-dopa . . . cause involuntary movements in all areas of the body, including the mouth" (4). The association of tricyclic treatment to oral dyskinesia has been reported (1, 2), and a recent publication described the occurrence of these symptoms with the prolonged use of antihistaminic decongestants (5). Crane noted that dyskinesias associated with drugs other than neuroleptics tend to subside once the drugs are discontinued. He also pointed out that organic conditions such as Huntington's chorea should be considered in the differential diagnosis of dyskinetic symptomatology (4).

Research on neuroleptic-induced tardive dyskinesia indicates that it is caused by dopamine hypersensitivity due to prolonged neuronal blocking. L-Dopa and amphetamines directly potentiate central dopaminergic

activity. In addition, the anticholinergic property of psychotropic drugs, especially the tricyclics, is considered a factor in the etiology of dyskinetic symptoms because of their influence on the dopaminergic/cholinergic balance within the brain.

Studies of brain mechanisms associated with benzodiazepines are less conclusive, but there have been indications of interaction with neurotransmitters, including γ-aminobutyric acid (GABA), glycine, norepinephrine, and serotonin. For example, benzodiazepines may mimic GABA's presynaptic inhibition at the serotonin nerve terminal (6). One might speculate that a compensatory reaction to this inhibition could develop after prolonged benzodiazepine treatment. Further research is necessary to determine the mechanisms involved in the actions of benzodiazepines on the CNS. However, we thought it important to report this unusual occurrence of tardive dyskinesia-like symptoms during ongoing low-dose benzodiazepine treatment. It is suggested that clinicians consider this possibility when treating cases of involuntary oral-buccal movements in patients whose drug regimen [illegible] zodiazepine treatment. Further considera[illegible] tionship between tardive dyskinesia-lik[illegible] and benzodiazepine treatment requires c[illegible] clinical observations.

Hyperkinesis and Diet: A Replication Study

BY FLORENCE LEVY, M.B.B.S., M.R.A.N.Z.C.P., M.P.H., AND GARY HOBBES, M.COMM.

There has been considerable recent controversy about the claims of Feingold (1) regarding the effects of artificial colors and food additives on hyperactivity in children (2, 3). A controlled study by Harley (4) failed to show any differences between children on the Feingold diet (known as the K-P diet) and a placebo diet. A double-blind crossover trial conducted by Conners and associates (5) found a significant reduction in symptoms of children on the K-P diet as rated by teachers.

Goyette and associates[1] have studied a sample of children selected by the following criteria: 1) a reduction of at least 25% in symptoms as rated by the mother on the Conners Hyperkinesis Index (6), 2) a behavioral and clinical diagnosis of hyperkinesis, and 3) baseline scores of at least 15 on mothers' and clinicians' ratings of the Hyperkinesis Index.

In the Goyette and associates study, eight subjects (mean age=5.3 years, range=3.4–8.4) met the full criteria, and five other children were border[illegible] ers. All subjects participated in a single 2[illegible] over trial with daily ratings by parents for a [illegible] riod after subjects ingested cookies cont[illegible] food colorings currently approved by t[illegible] Drug Administration or placebo. These [illegible] found a significant challenge effect in a Gr[illegible] × Challenge analysis of variance.

Levy and associates (7) reported a [illegible] crossover trial of the Feingold diet in whi[illegible] a tartrazine challenge. The children were [illegible] and after 4 weeks on the elimination die[illegible] weeks of tartrazine or placebo challenge. [illegible] scale scores and objective tests showed [illegible] differences in the behavior of the childre[illegible] during the challenge period. However, [illegible] thors tested a subgroup of the children se[illegible] basis of a 25% reduction in symptoms[illegible] there was a significant challenge effect.

Method

The present study attempted to r[illegible] Goyette and associates unpublished stud[illegible] same selection criteria, rating scale (the [illegible] Index), and instructions to parents on ra[illegible] dren. Challenge or placebo cookies wer[illegible] domly over 14 days. One difference from [illegible]

Dr. Levy is Staff Pediatric Psychiatrist, Avoca Clinic for Families and Children, Prince of Wales Children's Hospital, High St., Randwick, N.S.W. 2031, Australia, and Mr. Hobbes is Statistician and medical student, University of New South Wales.

[1]Unpublished data from C.H. Goyette, C.K. Conners, T.A. Petti, et al.

0002-953X/78/0012-1559$0.35 © 1978 American Psychiatric Association

and associates study was that the challenge consisted of tartrazine only (yellow dye number 5), whereas Goyette and associates used a mixture of food colorings approved by the FDA. The children ingested 4 cookies containing 1 mg of tartrazine each.

Results

Eight subjects met the study criteria. There was 1 dropout, a child whose parents claimed he became worse after ingesting the challenge cookies for 3 days. The average age of the children was 5 years, 2 months. There were seven boys and 1 girl. A Subjects × Treatment analysis of variance indicated no significant interaction. The mothers' scores on the Conners Scale were an average of 2.6 points higher during the challenge. However, this treatment effect just failed to reach the .05 level of significance. Global assessments by the mothers showed no significant differences in distinguishing active from inactive cookies. Thus the study did not replicate the significant challenge effect found by Goyette and associates. However, the 2.6-point difference in mothers' scores on the challenge versus placebo represented a 13% drop on placebo cookies from the initial average score of 20.5.

Discussion

The results may have been affected by the sample size—it was difficult to obtain a large sample of children who met all the selection criteria. In addition, the use of a symptom rating scale for assessing small or transient differences in hyperkinetic children has inherent problems; the differences rated by parents may be statistically significant but may not represent important clinical effects, or vice versa.

A further study reported by Conners and associates (5) found no significant differences in parental ratings during double-blind testing. However, an objective tracking test of attention showed a trend toward deterioration 1–2 hours after subjects ingested challenge materials. It is important that future studies of diet effects (and medication effects) use objective tests rather than the less reliable rating scales.

Tricyclics, Bioequivalence, and Clinical Response

BY ROBERT B. OSTROFF, M.D., AND JOHN P. DOCHERTY, M.D.

Tricyclic antidepressants are used widely in the treatment of depression (1). Much evidence has accumulated linking plasma levels of these drugs to therapeutic response (2–4). This evidence highlights the importance of comparing the bioequivalences of currently available tricyclic preparations both among various brands and within specific brands. Bioequivalence refers to the equivalence of the target biological activity, e.g., postsynaptic neuronal stimulation. In terms of the clinical use of tricyclics, bioequivalence, which is used interchangeably with the term "bioavailability," reflects the rate of absorption and the amount available for absorption of the active ingredient into the circulation (5). The following case illustrates the clinical importance of plasma drug levels and bioequivalence in the use of tricyclic antidepressants.

Case Report

The patient, a 56-year-old married man, stated that he came to the psychiatric clinic "because my doctor sent me." He had had one brief psychiatric hospitalization 38 years previously for depression. In the intervening years he had been without symptoms and without psychiatric contact. In the initial interview he was noted to have marked motor retardation, with constriction of affect and concrete thinking. He had had significant stressful familial and marital problems and complained of a 2-month history of anorexia, a 4.5-kg

Dr. Ostroff is Postgraduate Fellow, Department of Psychiatry, Yale University School of Medicine, where Dr. Docherty is Assistant Professor of Psychiatry.  0002-953X/78/0012-1560$0.35 © 1978 American Psychiatric Association

weight loss, early morning awakening, difficulty falling asleep, crying spells, feelings of hopelessness, and suicidal thoughts. He was not delusional.

He was started on 50 mg/day of amitriptyline and seen subsequently in couples therapy. Three days later, when no adverse drug effects were noted, the dosage of amitriptyline was increased to 100 mg q.h.s. He reported an immediate improvement in his sleep disturbance. At the end of week 2, his dosage was increased to 100 mg q.h.s. and 50 mg q.a.m.

At the end of week 4, the patient appeared at a couples session with a smile on his face. His expression was animated, the motor retardation was gone, and he reported improved appetite and complete amelioration of his dysphoria. At that session his prescription for amitriptyline was renewed. Three weeks later he came to a session appearing as depressed as he had initially. He complained of early morning awakening, difficulty falling asleep, loss of appetite, depression, and feelings of hopelessness. He admitted that he had taken an extra amitriptyline tablet during the week, but both he and his wife confirmed that this was the only such instance. There were no dynamic stresses. His amitriptyline was increased to 150 mg q.h.s. and 50 mg q.a.m., but his symptoms remained unchanged a week later. He was taking no other medications, including antacids, and had not been ill. He denied gastrointestinal disturbances and diarrhea. The couple's therapist (R.O.) was puzzled about the change in the patient's requirement for medication.

The amitriptyline dosage was increased to 200 mg q.h.s. and 50 mg q.a.m. One week later he reported a complete amelioration of his symptoms. At that point, the hospital pharmacy's record was reviewed. It was discovered that the pharmacy stocked two different manufacturers' brands of amitriptyline, one in 25-mg tablets (brand A) and the other in 50-mg tablets (brand B). The patient's dosage had been increased in increments of 25 mg (brand A) until he had a therapeutic response. When he renewed his prescription, he was given the 50-mg tablets. He required 250 mg of this product to achieve the response he had on 150 mg of brand A. A plasma level was obtained and the medication was changed back to brand A, 150 mg/day. One week later plasma levels were again determined. Plasma levels were determined on both doses and brands, with samples taken 8 hours after his last dose. The levels on the 250-mg dose of brand B were 18 ng/ml of amitriptyline and 23 ng/ml of nortriptyline. Levels on 150 mg of brand A were 29 ng/ml of amitriptyline and 45 ng/ml of nortriptyline. Six weeks later the patient remained symptom-free on 150 mg of brand A amitriptyline.

Discussion

There is substantial evidence that a minimum plasma level of a tricyclic compound is essential to therapeutic response (4). If the bioequivalence of tricyclics varies from manufacturer to manufacturer for the same compound, or from batch to batch produced by one manufacturer, then patients will achieve different plasma levels even though they are being given identical amounts of the active ingredie[nt] ... the Food and Drug Administration propo[ses] ... lations to establish a bioequivalence re[quirement] ... certain oral drugs in this category, inclu[ding] ... monly used amitriptyline and imipramin[e] ... rivatives. In the proposal it is stated th[at] ... data suggest that the various marketed ... same oral tricyclic antidepressant may ... parable therapeutic effects" (6). Many ... pharmacists to substitute various brand ... agent. The case we have reported sugg[ests] ... the digitalis preparations, tricyclics s[hould] ... scribed by brand name. The prescrib[er] ... should be aware that bioequivalence ma[y] ... between compounds and that, unless s[pecifically] ... structed not to do so, pharmacists in ma[ny] ... substitute preparations containing the ... agent. Also, the bioequivalence for ... turer's preparation may vary if the ine[rt] ... are changed. One must be sure that the ... company variability in the preparation o[f] ... pound. Additionally, in terms of cost ... dosage requirements must be considere[d] ... cost effectiveness rather than simply ... cost. Baclofen in the Treatment of Tardive Dyskinesia

BY N.P. VASAVAN NAIR, M.D., RAMSES YASSA, M.D., JOAQUIN RUIZ-NAVARRO, M.D., AND GEORGE SCHWARTZ, B.SC.

Tardive dyskinesias are involuntary stereotyped hyperkinesias that may develop during and after long-term treatment with neuroleptics. Although the exact pathogenesis of tardive dyskinesia is unknown, the current hypothesis is that neuroleptic drugs block striatal dopamine receptors (1), rendering these chemically denervated receptors hypersensitive (2).

Gamma-aminobutyric acid (GABA) is a major inhibitory neurotransmitter spread throughout the central nervous system. There is increasing evidence that the gabergic neuron system inhibits the dopaminergic nigrostriatal system (3). In animal studies, GABA agonists have been shown to inhibit the impluse flow in the nigrostriatal dopaminergic neurons (4) and to inhibit the release of dopamine into the synaptic cleft (5).

Baclofen (Lioresal, 4-amino-3-(4-chlorophenyl-butyric acid) is a GABA derivative that crosses the blood-brain barrier. It acts as a GABA agonist in inhibiting the striatal dopamine system (6). Korsgaard (7) and Gerlach and associates (8) found baclofen effective in tardive dyskinesia, whereas Simpson and associates (9) found it ineffective. The purpose of this study was to determine the efficacy of baclofen in a 3-week placebo-controlled crossover clinical trial.

Method

The subjects were 10 chronic schizophrenic patients (5 men and 5 women), ranging in age from 40 to 64 years (mean=56), who had been hospitalized for at least 20 years (mean=29) and had moderate to severe neuroleptic-induced tardive dyskinesia. Informed consent was obtained from the patients or their relatives.

All neuroleptic medications were withdrawn for at least 3 months. Patients were assigned randomly under double-blind conditions to receive baclofen or placebo for 3 weeks; they were then given a 2-week washout and a 3-week crossover. Baclofen dosage began with 30 mg/day, increasing gradually to 90 mg/day. The main evaluative instrument used was the Abnormal Involuntary Movement Scale (AIMS), which was recorded on videotape before and at the end of each 3-week phase of the study. In addition, the Clinical Global Impression (CGI) scale and the Brief Psychiatric Rating Scale (BPRS) were completed at the same time as the AIMS. Three psychiatrists rated the videotapes blind, and the mean AIMS scores were computed. Vital signs were taken daily and laboratory assessments were completed weekly.

Results

No statistically significant changes were found between baseline and the baclofen or placebo periods (Wilcoxon matched-pairs signed-ranks test). The mean sum of the first 7 movement scores of the AIMS before and at the end of placebo administration was unchanged at 8.8; mean scores increased slightly (from 10.9 to 11.5) in the baclofen condition. No significant changes were noted on the BPRS or CGI.

One woman patient developed severe loss of muscle tone toward the end of the baclofen period. No other side effects or significant changes on any of the laboratory measures and vital signs were noted for the group.

Discussion

Our finding that baclofen was not effective in the treatment of tardive dyskinesia is in agreement with that of Simpson and associates (9). Korsgaard (7) and Gerlach and associates (8) did find significant improvement in their patients' dyskinetic movements when baclofen was administered in combination with neuroleptic medications.

Our finding of a low incidence of side effects is also similar to those of Simpson and associates (9); Korsgaard (7) and Gerlach and associates (8) reported more side effects, but their patients were older and had various diagnoses, including dementia, which may have contributed to the increased incidence of side effects.

It appears, therefore, that baclofen when administered alone is ineffective in the treatment of neuroleptic-induced tardive dyskinesia in chronic schizophrenics.

Adult Minimal Brain Dysfunction and Schizophrenia: A Case Report

BY LEIGHTON Y. HUEY, M.D., MARK ZETIN, M.D., DAVID S. JANOWSKY, M.D., AND LEWIS L. JUDD, M.D.

Evidence exists that minimal brain dysfunction (MBD) may continue into adulthood in a variety of clinical manifestations (1-3). One group has reported that some adult patients with MBD respond favorably to psychostimulants, but patients with schizophrenia were excluded from that study (4). In addition, a subgroup of schizophrenics has been identified who are clinically responsive to psychostimulants (5) and who, unlike other schizophrenics, do not show an intensification of psychosis with such drugs (6).

The following case may be representative of a subgroup of individuals diagnosed as schizophrenic who have histories of childhood MBD. We postulate these individuals may have an adult variant of the MBD syndrome rather than schizophrenia per se and may be clinically responsive to treatment with psychostimulants rather than conventional neuroleptics.

Case Report

A 23-year-old man was admitted to the hospital with delusions of reference, complaints of auditory hallucinations, and feelings of confusion. He had a history of multiple hospitalizations during which he was diagnosed as schizophrenic and treated with neuroleptics, which were minimally effective. Past antipsychotic drug treatment had made him feel worse, and at no time did his auditory hallucinations disappear completely.

In childhood, the patient was seen by psychologists for behavior problems and hyperactivity, but he never received pharmacologic treatment. As a child he had been described with nervousness, inability to sit still, stubbornness, difficulty concentrating, temper tantrums, failure to complete tasks, fighting, bad handwriting, poor coordination, and general troublemaking.

In recent years, the patient had complained of restlessness, emotional overactivity, moodiness, poor concentration, impulsiveness, sloppiness, and poor coordination. He had occasionally used amphetamines because they seemed to have calmed him and made the hallucinations tolerable.

The clinical admission diagnosis was chronic undifferentiated schizophrenia. Using a structured diagnostic interview employing diagnostic criteria of Feighner and Spitzer, he was assigned a diagnosis of probable chronic undifferentiated schizophrenia. His full-scale IQ was 119.

Because of the patient's childhood history of MBD, he was enrolled (after giving informed consent) in a double-blind, placebo-controlled study to assess the effects of intravenous methylphenidate (0.5 mg/kg) on his psychiatric condition. The patient received placebo on day 1, followed by a 1-day drug washout and active methylphenidate on day 3.

He was interviewed on days 1 and 3. During the initial interview (placebo), the patient did not relate well to the physician, complained of active auditory hallucinations, and was anxious. He felt he was not "with" himself. His affect was markedly blunted. He displayed tremulousness in his extremities and in his facial movements. This tremor continued throughout the first session. During the interview on day 3, the patient initially appeared anxious and reported active auditory hallucinations, which were encouraging. After injection with methylphenidate, he stated the hallucinations faded into "babbling" and "noise." He became less anxious and was in better contact with the interviewer. He felt calm and more confident and reported feeling more able to focus on the tasks required during the session.

Four days after this interview, the patient was started on a double-blind trial comparing the effects of 4 days of oral placebo methylphenidate to 4 days of oral methylphenidate (10 mg b.i.d.).

Results

The results of the intravenous and the oral methylphenidate conditions are presented in Table 1. The oral

*Scores presented in T score form (mean=50, SD=10).

were some marked changes between the placebo and active intravenous trials. Changes were less pronounced for the oral phase of the study, perhaps because of the relatively low dose of methylphenidate. On the Beigel-Murphy Manic Rating Scale (8), the patient showed less distractability, irritability, and activity, and displayed better impulse control when challenged with active methylphenidate. During active medication phases, the NIMH Inpatient Behavioral Rating Scale indicated decreases in anxiety and tension, disorganized speech, hostility, excitement, hyperactivity, distractability, and increased affect. There appeared to be an increased sense of depression and uncertainty about the future.

On the Profile of Mood States there were decreases in scores on items measuring tension-anxiety, anger-hostility, and confusion-bewilderment during active drug administration. The patient also showed improved performance on the Trailmaking and Digit-Symbol Tests of the Halstead-Reitan Battery.

The changes seen with the oral methylphenidate, although less dramatic, paralleled those seen with the intravenous drug. The patient reported improved concentration and increased calmness during the oral active methylphenidate phase. He frequently read novels for long periods; when he was not receiving the drug his behavior was characterized by anxiousness and pacing.

The patient has been treated effectively for 4 months as an outpatient on 25 mg/day of oral methylphenidate. He reports improved ability to maintain good interpersonal relationships. On one occasion, the patient's methylphenidate was stolen and he was off the drug for 2 weeks. During that time, he reported a return of the auditory hallucinations, worsening concentration, and sleeplessness. Reinstitution of methylphenidate resulted in improvement of these signs and symptoms. During the outpatient program, the patient has never asked for an increase in his dose of methylphenidate or for extra medication.

Discussion

This case suggests it may be important to distinguish between those individuals who have schizophrenia and those who appear schizophrenic but may have an adult manifestation of MBD. Effective treatment for these groups may be different, with conventional neuroleptics being efficacious for schizophrenics, and psychostimulants, tricyclic antidepressants, or lithium having efficacy in those with adult MBD. Quitkin and associates (9) have described a group of schizophrenics, characterized by "soft neurologic signs," who showed improvement on imipramine. Furthermore, Handford (10) has hypothesized that individuals who experience brain hypoxia perinatally will be at risk for having minimal brain dysfunction in childhood and for subsequently developing schizophrenia as adults, possibly secondary to damage to dopaminergic pathways.

It has been suggested that minimal brain dysfunction can persist well into adulthood and may be concealed by other diagnoses, including sociopathy, explosive personality, hysterical character, and labile personality (4). We believe schizophrenia could be added to this list and propose that some adult patients diagnosed as schizophrenic may have a variant of the MBD syndrome. We speculate that some of the schizophrenics who show favorable responses to psychostimulants may be those having childhood histories of MBD or an adult variant of MBD.

Phenelzine and Delusions of Parasitosis: A Case Report

BY MICHAEL R. LIEBOWITZ, M.D., ERIC J. NUETZEL, M.D., ANSTISS E. BOWSER, M.S.W., AND DONALD F. KLEIN, M.D.

A delusion of parasitosis is the firm, fixed (mistaken) belief that one is infested by parasites. The phenomenon occurs with the use of psychostimulants—particularly amphetamines, cocaine (1), and methylphenidate (2)—and as a form of monosymptomatic hypochondriacal psychosis (3). Similar phenomena occur in various disease entities such as temporal lobe epilepsy, schizophrenia, and delirium tremens (4).

A variety of adverse effects have been reported with monoamine oxidase inhibitors (MAOIs), including psychosis, mania, and delirium (5), but we are unaware of any reports of delusions of parasitosis associated with this class of drugs. In fact, MAOIs have recently been advocated in the treatment of such delusions (6). The following case illustrates delusions of parasitosis in a patient taking MAOIs.

Case Report

Ms. A, a married office-worker in her late 20s, sought outpatient treatment for depression and marital difficulties. Her history included recurrent depressive episodes in response to feeling rejected. These nonautonomous episodes were characterized by tearfulness, social withdrawal, suicidal thoughts, decreased energy, overeating, and oversleeping, comprising a syndrome termed hysteroid dysphoria (7).

The patient had no history of mania or psychosis, although she had experienced transient visual and tactile hallucinations while smoking marijuana. She denied sedative abuse and use of hallucinogens or cocaine, and she had avoided marijuana for several years before we saw [illegible] phetamine use had consisted of up to four [illegible] several months 8 years earlier. Her alcohol u[illegible] ly light, and she had a stable work history. Wh[illegible] depressed, Ms. A was outgoing and vivacious [illegible] history and results of a physical examination [illegible]

Ms. A was treated with psychotherapy and [illegible] phenelzine in a maintenance program for hys[illegible] ics after the procedures were fully explained [illegible] informed consent to participate. The phenelz[illegible] increased to 60 mg/day over the next several [illegible] reduced to 45 mg/day during the 8th week of [illegible] Ms. A became overstimulated. She appeared [illegible] functional and happy on this dose for the ne[illegible]

During the 18th week of treatment, while [illegible] 45 mg/day of phenelzine, Ms. A reported to h[illegible] her body and hair were infested with small bl[illegible] had first noticed a painful itching all over her [illegible] followed by the sensation of things crawling [illegible] She said tiny black objects fell from her hair, [illegible] her clothing, burrowed into her skin, and ca[illegible] her pores. She consulted a dermatologist, w[illegible] festation. She also saw long, black, hairlike [illegible] in her stool and consulted an internist, who [illegible] fibers. During psychotherapy sessions, [illegible] scratched and picked at herself, sometimes [illegible] aware of this behavior and at other times dis[illegible]

Ms. A's mental status at this time was char[illegible] line only in that she was less depressed and [illegible] tactile hallucinations and a delusional belief [illegible] She was oriented in all spheres, had no cog[illegible] ment, and continued to work throughout the [illegible] phenelzine was discontinued, the itching dec[illegible] biting, crawling, and pinching sensations sto[illegible] Ms. A continued to see small black objects fa[illegible] but she now believed they were particles from [illegible] ing or vent. Over the next 3 months her itch r[illegible] of the scalp, visualization of small black ob[illegible] cern with environmental pollutants gradually [illegible] ing this period physical examination and lab[illegible] ing were normal, except for borderline vitam[illegible] serum B_{12} levels, which were treated with ora[illegible]

After 4 months off medication, Ms. A was a[illegible] and was restarted on phenelzine, 15 mg/day [illegible]

The authors are with the College of Physicians and Surgeons, Columbia University, where Dr. Liebowitz is Instructor in Clinical Psychiatry, Dr. Nuetzel is Resident in Psychiatry, Ms. Bowser is Assistant in Clinical Psychiatry, and Dr. Klein is Professor of Psychiatry. They are also with the New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Liebowitz is Research Fellow, Dr. Nuetzel is Resident, Ms. Bowser is Social Worker, Depression Evaluation Service, and Dr. Klein is Director of Research.

The authors would like to thank Dr. Sidney Malitz, College of Physicians and Surgeons, Columbia University, for psychotherapy supervision; and Dr. Herman Baker of the College of Medicine and Dentistry of New Jersey for serum vitamin assays.

0002-953X/78/0012-1565$0.35 © 1978 American Psychiatric Association

she reported the feeling that bugs were crawling on her skin and scalp, and she saw numerous black moving spots when looking at light-colored surfaces. The experience was identical with the previous one, except that this time it was attributed by the patient to medication. Serum vitamin levels were normal, and the symptoms disappeared within several days after she was switched to placebo phenelzine in a single-blind manner.

Two nonhydrazine MAOIs were then tried on a nonblind basis with 10-day drug-free periods before each. Tranylcypromine, 10 mg/day, produced severe abdominal cramping and constipation after 3 days and was discontinued. She was then given pargyline, 10 mg/day, and after 4 days reported seeing gray-black spots and feeling crawling and pinching sensations of scalp and pubic regions. This made her wonder whether she was infested with lice. An antidepressant effect was noted on day 6, but the drug was discontinued the next day because of its side effects.

Discussion

A variety of mechanisms have been offered to explain psychostimulant-induced psychoses. Amphetamine potentiates several catecholamines, but attempts to assess relative dopaminergic and noradrenergic effects through behavioral and neurochemical studies have produced conflicting results (8). Post and Kopanda (9) suggested an interaction of catecholamine potentiation and pharmacological kindling or sensitization of limbic structures to explain cocaine's effects. Ellinwood (1) argued that amphetamine-induced delusions of parasitosis are an extension of stereotyped grooming and picking responses in association with abnormal skin sensations that may be peripherally mediated. Finally, Siegel (10) speculated that cocaine hallucinations evolve from drug-induced tactile sensations and visual phenomena.

Our patient's delusion of parasitosis, evolving in a clear sensorium, was indistinguishable from those previously reported with psychostimulant use. Phenelzine is clearly implicated: the delusions appeared after 4½ months of phenelzine use, gradually waned when the drug was discontinued, reappeared soon after it was reinstituted, and disappeared after a single-blind switch to placebo. The reappearance of similar symptoms when the patient was taking a low dose of pargyline implies that the effect is not dependent on hydrazine toxicity.

Several inferences can be made with regard to pathophysiology. This patient's periods of behavioral overstimulation and delusional belief were temporally distinct, which indicates that they were mediated by different mechanisms. That she also showed a reverse tolerance to the drug supports the involvement of a kindling mechanism. Most significantly, her delusion of parasitosis seemed elaborated from a combination of abnormal skin sensations and visual phenomena, similar to the hypothesis proposed by Siegel for cocaine (10).

One can also speculate on other mechanisms. Peripheral nerve effects may play a role, although repeated assays failed to confirm suspected vitamin abnormalities. Trace substances such as phenylethylamine may accumulate, adversely affecting a patient who has substantially inhibited MAO activity. Finally, this patient may have had an underlying vulnerability to visual and tactile hallucinations, as evidenced by her past reactions to marijuana.

The case is presented to elucidate further the etiology of psychostimulant-induced psychoses and to alert physicians who prescribe MAOIs. We recommend careful monitoring of any patient with a history of even brief psychotic experiences and discontinuation of the drug should these symptoms develop.

We regret that we [illegible] writers of the disposition of letters or return those which are not printed.*

Policy of the APA Ethics Committee

SIR: In the February 1978 issue Robert A. Moore, M.D., published his interesting and informative article, "Ethics in the Practice of Psychiatry." The paragraph on due process may be misunderstood and is in need of clarification. In that paragraph, Dr. Moore advocated that ethics committees investigate complaints and hold hearings according to the adversary model of criminal justice, including confrontation and cross-examination of the complainant. Although that article did not appear in the buff pages (reserved for official actions of APA) in the *Journal* and therefore should be clearly understood to reflect only Dr. Moore's personal opinion, at the time the article was published Dr. Moore was Chairperson of the American Psychiatric Association Ethics Committee and, in fact, made such procedures the policy of the APA Ethics Committee when it acted in the capacity of initial investigating body. Thus, some might (and indeed at the Ethics Workship, Course 7, at the annual meeting, one lawyer did) justifiably but mistakenly think Dr. Moore's statement reflected not merely his personal opinion but the policy of APA as well.

In fact, the APA Constitution and By-Laws and the Procedures for Handling Complaints of Unethical Conduct (Revised 1977) make no statement prescribing or recommending a formal "hearing." Rather, they state that the complainant must file a complaint in writing and that the investigating body "permit both the defendant and complainant to be heard," allowing greater flexibility for ethics committees to tailor their procedures to the needs of individual cases.

The official position of APA is consonant with that of the American Medical Association Judicial Council Opinions and Reports (1) (by which APA would not be bound, since we are a separate organization) and is supported by legal precedents concerning disciplinary proceedings by professional societies and other membership organizations. For example, to quote the California Supreme Court from the Pinsker decision mentioned by Dr. Moore (in which exclusion determined as equivalent to expulsion was at issue):

> The common law requirement of a fair procedure does not compel formal proceedings with all the embellishments of a court trial . . . nor adherence to a single mode of process. It may be satisfied by any one of a variety of procedures which afford a fair opportunity for an applicant to present his position . . . The [illegible] themselves should retain the initial and pri[illegible] sibility for devising a method which provi[illegible] quate notice of the 'charges' . . . and a re[illegible] portunity to respond. In drafting such pro[illegible] determining, for example, whether an appl[illegible] given an opportunity to respond in writing [illegible] sonal appearance, the organizaiton should [illegible] nature of tendered issue and should fashi[illegible] dure to insure a *fair* opportunity for an app[illegible] sent his position. (2)

Thus, the procedures advocated by Dr Mo[illegible] required nor recommended by the official pol[illegible] by the AMA, or by legal precedent.

The Washington Psychiatric Society and A[illegible] (on whose behalf I am writing) strongly su[illegible] policy as it now stands. The adversary proc[illegible] mended by Dr. Moore, which are neither p[illegible] requirement, in our opinion do not represent [illegible] or ideal model. From our experience, we w[illegible] number of complaints filed would plummet [illegible] plainant had to attend an adversary heari[illegible] plainants, many of whom are patients in a pre[illegible] mental health, would be willing (nor do we be[illegible] willing) to subject themselves to cross-exami[illegible] gressive opposing attorney (and in his article [illegible] ommends the complainant not have the right t[illegible] legal counsel present). Furthermore, it has no[illegible] pression that following the adversary model [illegible] tice helps in uncovering the truth. Rather, i[illegible] experience that the more we have veered tow[illegible] sary model, the more we have become enme[illegible] dural technicalities and the harder it has be[illegible] the ethical concerns and recommend appropr[illegible]

Wash[illegible]

Dr. Moore Replies

SIR: While APA does have established procedures for the routing of ethical complaints and for appeals, it does not have procedures for how hearings should be conducted. To avoid any misunderstanding, my article should not be construed as an official position of APA.

Two years ago, the APA Ethics Committee held a workshop on hearings for its own education with a faculty consisting of the APA legal counsel, an American Civil Liberties Union attorney, and an attorney from the American Arbitration Association. The results of this workshop have been circulated to the District Branches and discussed at the last two workshops on ethics at the annual meeting. As in the article, this information has been presented for consideration as a hearing model, not as a mandate. Of course, situations differ so that no one model will be correct in all cases.

The issue of the right to challenge someone who brings charges against another is well established in due process. What constitutes "fairness" in a fair procedure is less clear. While we are urging greater activity in self-policing, this must not lead us to disregard what is "fair" for one of our members. I believe that an accused member has the right, in all fairness, to personally challenge his or her accuser. That right does not belong to the hearing body nor the accuser but to the accused. He or she may well decide to forego that right, especially if the accuser is a patient who might be harmed by such a confrontation.

A more important issue is whether we are erring by moving to more formal procedures. Unfortunately, in earlier years, our efforts at peer review and discipline were often subterranean and had a "clubby" quality that led our critics to say we were doing nothing and therefore they should do it for us. Further, accused members themselves, exercising their legal rights, have challenged such informality. The result has been greater formality and visibility to demonstrate we are capable of protecting the integrity of our profession without denying our members their rights.

While there may be differences of opinion, I am most impressed by the dedication to ethical principles and to their protection shown by Dr. Coleman and the Washington Psychiatric Society.

ROBERT A. MOORE, M.D.
San Diego, Calif.

Ethics in Military Medicine

SIR: I feel it is necessary to emphasize that the comments by Ransom Arthur, M.D. ("Reflections on Military Psychiatry," July 1978 supplement) on ethics and military medicine are his own highly personal conclusions and represent only one opinion on an issue worth studying more closely. Dr. Arthur's comments, in part by focusing on a reductio ad absurdum, would have us believe that all ethical questions regarding military psychiatry are "ethical fastidiousness," "ethical hypersensitivity," and "scrupulosity."

Dr. Arthur states that "it was only with the arrival of a war of stupendous unpopularity involving a nation possessed of unprecedented comfort and affluence that moral sensitivity arose about a number of war-related issues." Here he appears to lump genuine concern about ethical issues with radical chic. He neglects the growing legitimate (to my mind) questioning of inappropriate governmental activities in this country. This questioning has been more frequent since World War II, in part because some members of a new generation both experienced the McCarthy era and heard Eichmann say, "I was just following orders," and do not wish to see those mistakes repeated.

In addition, I would like to call into question one of Dr. Arthur's statements of fact. He states that "moral dilemmas of military medical practice were mentioned in works dealing with military psychiatry in both of the world wars but were quickly dismissed." Yet Lord Moran wrote in 1943, describing his feelings as a medical officer with the British Army in World War I:

> but what, I wonder, became of pity in those ruthless years? When I look back I see that I was caught up in the atmosphere of the trenches. . . .
>
> I was perturbed at that time not by any difficulty in shaping opinion in the battalion, but by a gnawing anxiety lest the hard temper of the hour should drive men beyond what is fair and just. . . . Even now after twenty years my own conscience is troubled by the summary judgements passed on some poor wretch in those days, and by my own part in those verdicts. (1, p. 177)

This statement was made by a distinguished physician who served as Churchill's doctor during World War II.

Finally, Dr. Arthur states that "in any case, with the ending of America's direct participation in war, the moral issues of combat psychiatry are now moot." This is untrue. It is precisely now, some time removed from "the atmosphere of the trenches," that we can reflect more soberly on these issues. We need to sharpen our thinking in this area, not only to be prepared for future wars, but also because we need to be aware of the potential role conflicts that inevitably occur in any psychiatric setting (2).

The issue is too emotion-laden and too complicated to be dealt with merely by part of an article and by an exchange of letters to the Editor. It deserves a more extensive look.

Dr. Arthur Replies

SIR: I had hoped that my comments on the changing ethical climate of military psychiatry would provoke some thought and further ideas. I am pleased to see that they have done so.

The interpretation that I implied that all ethical questions regarding military psychiatry are merely the results of ethical hypersensitivity is a misreading of the text. If the topic of ethics in military medicine did not have real substance, it would not have been included in the essay.

I stand behind my statement that the Viet Nam war and the recent tumult about ethics in government have produced a vastly different social and intellectual climate for the consideration of such questions than was the case during and after World Wars I and II. There really were no organized

general, and explicit statements of moral opposition to the provision of medical services per se (including psychiatric services) to the military, during either world war. Naturally there were, as always, individual acts of protest against war itself (Bertrand Russell's, for example) but certainly no "movement" against military medicine as such. A rereading of *The Anatomy of Courage* leads to the interpretation that the remarks quoted by Dr. Perlman are reflective of Lord Moran's experience with effects on morale of gas warfare rather than an indictment of military physicians. In fact, he indicates on a subsequent page, "But in this life the individual shrinks to nothing, he has no longer the right to an opinion, only the regiment matters" (1). During World War I, Lord Moran served as the battalion medical officer for the First Royal Fusiliers (the initial regular battalion) from 1914 to 1917. Although he was obviously ambivalent about war—admiring the courage and example of units like the Brigade of Guards but deploring the misery, squalor, and loss of life attendant upon armed struggle—he never puts forth any conceptualization of an explicit conflict between his role as a physician and his role as an officer of the Fusiliers. Whatever his private doubts may have been, he did his duty as a medical officer throughout his active service on the Western Front. On the other hand, the Viet Nam war occasioned overt public criticisms of military medicine. During that war, publicity was given to possible moral conflicts between one's duty as a physician and one's duty as a member of a nation's armed forces.

Of course, there should be rational debate on these issues, but discussion can be unnecessarily envenomed by the intense emotion that still colors any thoughts about that horrid war in Southeast Asia. I recently reviewed a book dealing with certain psychiatric problems of the Viet Nam war. A striking feature of many of the excellent essays was the sense of general rage expressed by the authors. There was a tone of vituperation directed toward all manner of institutions, which could not be more different from the tone of works like *Psychiatry in a Troubled World* (2), which dealt with the events of World War II. I think we should be discussing the ethical constraints asked by the modern world of a military physician. However, genuinely fruitful discussion will be difficult until some of the indignation has diminished and a certain degree of dispassion and objectivity is attained.

Dangers of Indirect Data

SIR: In the June 1978 issue there was an extremely useful and informative article on "The Opiate Receptor and Morphine-Like Peptides in the Brain," by Solomon H. Snyder, M.D., who is famous for contributions to neurobiology, particularly the biochemical aspects of psychiatric disorders. We all know that collecting meaningful data from patients with psychiatric disorders is very difficult—patient characteristics cannot be controlled like those of experimental animals, and human considerations make it almost impossible to collect data from the living, functioning [illegible]. I [illegible] ce[illegible] sequence, there has developed a large bod[illegible] lite[illegible] based on indirect data.

There is a potentially misleading passage in [illegible]rap[illegible] illustrates some typical consequences of the [illegible] of [illegible] data. The passage begins as follows: "A leu[illegible]-com[illegible] β-endorphin molecule has been reported in [illegible]ey[illegible] schizophrenics undergoing hemodialysis (75 [illegible]Wa[illegible] ker, personal communication)" (p. 650). The[illegible] m[illegible] of findings in controls, so it is not clear whe[illegible] om[illegible]h specific to schizophrenia was observed. The [illegible] ues, "Wagemaker and Cade (personal com[illegible] [illegible]tic[illegible] ported that repeated hemodialysis increases [illegible]deg[illegible]e clinical improvement in schizophrenics." In [illegible]ss. of the *Journal* there was a paper (1) in whic[illegible] [illegible]sp[illegible] data from many centers showed no positive [illegible] fects of hemodialysis on 50 schizophrenic pa[illegible] failure. Perhaps Dr. Snyder was not familiar [illegible] os[illegible] ings, but the Editorial Board of the *Journal* c[illegible] municated them to him. There is great interes[illegible] on hemodialysis, and it is important that nega[illegible] communicated rapidly. (I should note that I [illegible] skeptical about the hemodialysis findings fro[illegible]

The author then notes, "Chemical analys[illegible] from these patients revealed the presence of [illegible] amino acid sequence was established as bein[illegible] that of β-endorphin except that the methioni[illegible] of β-endorphin was replaced by leucine. The f[illegible] id, could imply a single gene mutation in sc[illegible] The data given are not sufficient to propose [illegible] is irresponsible to add to the many works [illegible] schizophrenia that have already been writte[illegible] in the way of definite data. Dr. Snyder must [illegible] data are necessary to postulate such a genetic [illegible] note that "whether schizophrenic and nor[illegible] differ reliably in levels of this substance has [illegible] ously established." Given this lack of data, I [illegible] passage should not have been published. T[illegible] passages like this in the literature, and some[illegible] tirely constructed of indirect and/or uncont[illegible] should stop publishing this uninformative ar[illegible] leading material.

Depressive Cognitions

SIR: In "Maladaptive Cognitive Structures in Depression" (May 1978 issue) Maria Kovacs, Ph.D., and Aaron T. Beck, M.D., outlined in a precise and scientific fashion which has long been known about some of the phenomenologic aspects of depression. These observations are consistent with empirical observations by psychiatrists and physicians and more or less intuitive general knowledge about depression.

At this point, however, the authors interpret in a causative role what others have considered to be merely the symptoms or effects of depression. Some effort is made to affirm that these cognitive patterns and mechanisms are present in depressed patients, and this is done rather convincingly.

The "proof of the pudding," however, would seem to await a study showing that what the authors have labeled "depressive cognitions" are present in patients with histories of recurrent depressions while their depressions are in complete remission. Presumably, this would not be the case with a matched control group of nondepressed normal people. Such a finding would more convincingly establish these depressive cognitions as part of the patient's underlying personality structure rather than symptoms resulting from the depressive syndrome itself.

I hope that such a study will be forthcoming from the authors.

MARK T. SCHREIBER, M.D.
St. Louis, Mo.

Drs. Kovacs and Beck Reply

SIR: We appreciate Dr. Schreiber's positive comments about our article and would like to respond to two interesting issues he raises regarding the cognitive model of depression.

First, Dr. Schreiber alludes to the traditional concept that depressive cognitions are basically "symptoms or effects of depression," as opposed to the more salient role we emphasized. Second, he says we have not shown depressive cognitions to be part of the depression-prone individual's personality (or cognitive) organization.

The first question relates to the primacy of cognitive factors in the depressive syndrome. In many contemporary descriptions, depression is regarded as an affective disorder, pure and simple, and its cognitive manifestations are largely ignored. However, we have attempted to make some sense out of the highly diverse symptoms by arranging them in a coherent logical sequence.

In taking a "cross-section" of depressive symptomatology, we look for the primary psychopathology in the peculiar way the individual views himself, his experiences, and his future, and in his idiosyncratic way of processing information. The postulate that the patient's negative construction of reality is the first link in the chain of symptoms provides a range of hypotheses, many of which have been tested and supported in over two dozen studies (1). A recent review of cognitive behavior therapy in the treatment of unipolar depression (2) cited 10 additional outcome studies which report that techniques derived from this model appear to be more effective than comparison treatments. (We are aware, of course, that the efficacy of therapy does not prove the underlying theory).

Therefore, at this stage, we can state with some minimal level of confidence that the cognitive model has a greater explanatory power of the phenomena of depression than other psychological models presented to date. The model, however, does not address the ultimate etiology or cause of unipolar depression, which may encompass hereditary predisposition, faulty learning, brain damage, biochemical abnormalities, or any combination thereof.

In regard to the role of underlying maladaptive personality traits, we base our case on logic and speculation. It does not seem plausible that the aberrant cognitive mechanisms are created de novo every time an individual experiences a depression. It appears more credible that an underlying predisposition (personality trait or cognitive structure) becomes activated when depression is precipitated by psychological stress, biochemical imbalance, hypothalamic stimulation, or whatever. The manner of activation of the depressogenic schemata has been formulated previously (3). In our article, we cited two relevant studies. Hauri (4) found that compared with controls *remitted* depressed patients showed a preponderance of characteristic negative dream themes and a predominant past time orientation. Weintraub and associates (5) reported that over a course of 5 testings, cognitive content was remarkably stable compared with affect. Based on the Weintraub and associates study, it would be a logical conclusion that in the organization of personality, a factor that is stable over time is more likely to have a causative role then an unstable one such as affect.

We certainly agree with Dr. Schreiber that the "proof of the pudding" resides in further investigations. There is an urgent need for longitudinal studies of depressed patients in remission. It would also be desirable to compare the cognitions of two groups of remitted depressed patients, one given cognitive therapy and one treated with chemotherapy. We could then test the hypothesis that cognitively treated remitted depressed patients are less likely to evidence the so-called depressogenic assumptions and cognitions than the comparison patients.

In summary, Dr. Schreiber's points are well taken, but his suggestion that the cognitive distortions result from an independent syndrome labeled depression has not yet received any empirical support.

Nutmeg Abuse

SIR: The case report in "Spice Cabinet Intoxication" by Robert A. Faguet, M.D., and Kay F. Rowland, Ph.D. (July 1978 issue) was of special interest to me as I had reported a similar case elsewhere (1). The patient reported by me had ingested two tablespoons of nutmeg and demonstrated an acute confusional state with visual hallucinations. The authors suggested that myristicin was the psychoactive ingredient responsible for the symptoms. However, it appears that the hallucinogenic properties of nutmeg are not caused by myristicin but by other volatile principles present in it, like eugenol, isoeugenol, geraniol, safrol, borneol, and linalool (2).

The usual toxic dose of nutmeg is about 5–15 g of powdered nutmeg, and toxicity in a majority of cases is usually accompanied by severe physical distress. Nutmeg abuse is not as rare as the authors suggest. Nutmeg poisoning was first documented in 1576, and since then there have been a number of reports of toxicity following intentional or accidental excessive use of nutmeg (3, 4). "Nutmeg high" was well known to the youth of the 60s, and convicts have always abused nutmeg.

Effects of Diagnostic Criteria on Incidence Figures for Schizophrenia

SIR: Michael Alan Taylor, M.D., and Richard Abrams, M.D., noted in "The Prevalence of Schizophrenia: A Reassessment Using Modern Diagnostic Criteria" (August 1978 issue) that narrow, rigorous criteria for a diagnosis of schizophrenia may result in a low incidence of schizophrenic admissions to a psychiatric inpatient service. However, at the Medical College of Virginia, we have noted a much higher admission incidence of schizophrenia than that reported by Drs. Taylor and Abrams.

As part of the clinical trials of *DSM-III*, we studied 67 inpatient admissions, aged 15–95 years, all of whom were interviewed by at least one of us. There was 10[illegible] agreement on diagnosis for all patients who were interviewed by [illegible] us. Of the 67 patients, 15 (22.4%) received [illegible] schizophrenic disorder. Overall, 15 of the 91 [illegible] diagnoses (16.5%) were of schizophrenia.

These data may be considered further evi[illegible] the low incidence of schizophrenia reported by D[illegible] and Abrams is solely a function of diagnostic rigo[illegible] for schizophrenia in the proposed *DSM-III* a[illegible] between Kraepelinian-Schneiderian narrowness [illegible] rian broadness. However, this is unlikely in [illegible] cause most of the schizophrenics had Schneid[illegible] symptoms and most met the research criteria [illegible] Taylor and Abrams.

Another explanation of the differences in in[illegible] the results are an artifact of the patient popu[illegible] Our hospital is a public urban teaching hospital [illegible] ly serves individuals in Hollingshead-Redlich [illegible] III–V. There is generally a higher rate of sc[illegible] these social classes than in social classes serv[illegible] urban center the authors studied. In addition, [illegible] atric hospitals in our locality "siphon" off pa[illegible] fective disorders, which leaves a patient poo[illegible] incidence of schizophrenia and which leads t[illegible] mission incidence of schizophrenics.

Editorial Double Standards?

SIR: The recent exchange of letters between Joseph Wolpe, M.D., and Silvano Arieti, M.D. ("Research Methodology," August 1978 issue) concerning my criticism of the publication of Dr. Arieti's article "Psychotherapy of Severe Depression" (August 1977 issue, and letter in the January 1978 issue) forces me to conclude that we have all left the real culprits off the hook. I write of journal editors. Despite lengthy missives to the contrary, Dr. Arieti did not define his patient group in reproducible terms, did not use reliable and valid pre- and post-treatment measures of behavioral change (or any other change), did not use a comparison control group, and did not have an "unbiased" rater evaluate his patients after treatment.

My quarrel is not with Dr. Arieti; it was and is with the editor of this and most other psychiatric journals. If I were to submit an article about my favorite treatment modalities that had the same failings as Dr. Arieti's paper, I would receive a rejection letter, not to mention nasty reviews. This is a double standard. If I cannot get away with bad science, why can Dr. Arieti? Dr. Wolpe wrote about the "disdain some psychotherapists display for the rules of scientific research." If such disdain exists, it is because journal editors have allowed it to exist. Let the Editor end this double standard and explicitly state the rules of scientific research to which each article, no matter what its content, must adhere. I look forward to such a policy in the *American Journal of Psychiatry*.

MICHAEL A. TAYLOR, M.D.
Chicago, Ill.

Editor's Note. Although not certain that the writer's conclusions about editors were reached through the scientific procedures he espouses, we endorse the standards he implicitly proposes for the direction of the *Journal*. We will pursue them diligently, secure in the knowledge that when the fallibility of human judgment leads us into an occasional falling from grace, it will not be met by silence.

J.C.N.

Cause and Effect in "Alcoholic Tremor"

SIR: Many patients and physicians point to alcohol toxicity as the cause of a tremor, and "alcoholic tremor" has been well described. However, it is important to note that some alcoholic patients began drinking alcohol because of a tremor. We have seven patients who have definitely stated that they started drinking alcohol because alcohol relieved their tremor. As the need seemed to be continuous, the drinking became more and more essential.

Benign essential (familial) tremor is a common condition manifested by trembling or involuntary rhythmic movement of the body, usually upper limbs or head. It most commonly starts in adulthood (1), affects both sexes, and may progress slowly. Often, there is evidence of a dominant inheritance pattern (2). No consistent pathology has been found (3).

The rate of the tremor is generally in the range of 4–12/second, and it may be an exaggeration of normal tremor (4). It is present at rest and may be inhibited temporarily by volition. However, it becomes worse when the patient is under stress or is being observed and improves when he or she is tranquil or in repose. Fatigue usually increases the tremor. Neurologic examination is otherwise normal. These patients often report improvement after alcohol intake. Treatment consists of various drug therapies (e.g., propranolol) or simply reassurance.

We feel that preexistent benign tremor may play a role in some patients' initial use of alcohol and that not all tremors in alcoholics are due to excessive alcohol intake.

Speech Blockage in Young Patients Taking Tricyclics

SIR: In their recent article "Speech Blockage: A Tricyclic Side Effect" (May 1978 issue) Alan F. Schatzberg, M.D., Jonathan O. Cole, M.D., and Dietrich P. Blumer, M.D., reported on five patients who developed a previously undescribed side effect of tricyclic antidepressants, "speech blockage." In their communication they described this as an inability to find and translate words into speech, leading to pauses in conversation which could be confused with the "blocking" seen in schizophrenic patients. Four of their five patients were over age 40 and the fifth patient was 36, so they suggested this side effect to be more common in older patients. They attempted to explain this phenomenon as resulting from a central anticholinergic effect on higher cortical functions or, alternatively, from "a relative decrease in cholinergic activity secondary to a tricyclic-related increase of noradrenergic activity."

I wish to report another case of speech blockage, this occurring in a 25-year-old man. The patient, a married man, sought treatment for a depression of several months' duration characterized by insomnia, loss of appetite with slight weight loss, diminished interest in usual activities, headaches, abdominal discomfort, palpitations, poor concentration, and depressed mood with feelings of hopelessness and worthlessness. He was begun on amitriptyline alone, 75 mg/day, which was increased to 100 mg after one week. After another week he experienced what he described as difficulty in "getting my words out" and feeling like his "mouth muscles wouldn't work" for a few seconds at a time. The "blockage" occurred unpredictably in conversation, sometimes in midsentence. Sometimes he could only articulate one syllable of a word but after trying a few seconds he would be able to complete the sentence. He reported no difficulty finding or thinking of words but rather in translating the word from thought to speech. When the amitriptyline was increased to 125 mg, the effect became worse and the medication had to be discontinued. Within 2 days, his speech returned to normal. He was then started on imipramine and increased to 150 mg over 10 days, during which he experienced one transient episode of speech blockage. This did not recur again while

he was continued on 150 mg, and his depression resolved completely over the next 2 weeks.

Unlike the cases reported by Schatzberg and associates, this patient was young, in his 20s. Also unlike the reported cases, the patient denied difficulty "finding" words but rather could not convert a conceived word into actual speech. In agreement with their description, however, this patient showed no evidence of a toxic-confusional state, nor was his speech slurred. He had no problem articulating or pronouncing words; rather, there was brief but complete cessation of the speech process.

It is of interest to note that along with speech blockage, he also experienced occasional difficulty with recent memory, an effect previously reported with tricyclics (1). Schatzberg and associates did not state whether their patients also experienced memory impairment, but this might be important in view of their description of difficulty with word retrieval as part of speech blockage. It is not clear, for example, whether speech blockage might be related to a transient disturbance of memory, or to an aphasic or apraxic phenomenon.

Although I have treated hundreds of patients with tricyclic drugs, this is the first patient in my experience to report this side effect. Whether this reflects a lack of awareness or a low incidence of its occurrence is unclear. As this case illustrates, however, clinical awareness of this side effect of tricyclic antidepressants must now be extended to younger patients as well.

ALAN J. SHOLOMSKAS, M.D.
New Haven, Conn.

Drs. Schatzberg and Cole Reply

SIR: We were pleased to read Dr. Sholomskas' report of another case of speech blockage. His patient showed some difficulty with memory that our patients did not demonstrate. We have seen and reported on mild memory difficulty with tricyclic antidepressants in another group of patients (1). It is difficult to determine whether the symptom reflects a central hesitance in thinking or a hesitance in translating the "cognitive thought" into words. This is in part a matter of differentiation. Our patients did not appear to be aphasic. Dr. Sholomskas' observation that the symptom can occur in a young patient should alert us to look for such symptoms in patients on tricyclics. We believe the symptom is more common than it may appear. Since our report I have seen several other cases and other clinicians have reported cases to me. One last point, which we raised in a previous letter, regards the question of some patients with stammering having myoclonic jerks of facial musculatry. This is not clear from Dr. Sholomskas' letter but may have been a contributing factor in that the patient felt like "his mouth muscles wouldn't work." Was this a descriptive statement of the symptom or did the patient in fact demonstrate some involuntary facial jerks or difficulty in phonation? We believe that our patients' difficulties were primarily related to the central anticholinergic effects of the drugs. However, to prove this is difficult.

Again, we wish to thank Dr. Sholomskas for his contribution of reporting another case of "speech blockage."

Treating the Impaired Physician

SIR: The American Medical Association's C[illegible] of Ethical Ethics make it clear that physicians are [illegible] help faltering colleagues. It is less clear how [illegible] this.

Impaired physicians may benefit from syst[illegible] plemented, practical programs of casefindi[illegible] vention, in which psychiatrists actively pa[illegible] Michigan Psychiatric Society recently urged [illegible] APA program aimed at three groups: the seriou[illegible] those troubled but still capable of practicing [illegible] trainees (1). Your readers may be interested i[illegible] mendations outlined below, since the burden o[illegible] turbed colleagues falls most heavily on psych[illegible]

The seriously impaired physician. He/she us[illegible] ous, on the brink of professional ruin, and re[illegible] rehabilitative effort, including the following:

1. Crisis teams with psychiatric direction, t[illegible] ry out intervention.
2. Financial advice and emergency loans.
3. A *locum tenens* roster (perhaps of recent[illegible] still effective physicians) to replace a faltering [illegible] can get back on his feet.
4. A national network of residential treatm[illegible] impaired physicians, with free services for th[illegible] pay (2).
5. Health insurance adequate to cover both [illegible] outpatient therapy.
6. Emotional support and guidance for t[illegible] family.

The troubled but still practicing physician. [illegible] those in this category include the following:

1. Improved casefinding and highlighting o[illegible] ty of voluntary, confidential help for the phys[illegible] family.
2. Information and assistance to the spous[illegible] the key to obtaining diagnosis and treatment [illegible] cian.
3. A roster of physicians in each state wh[illegible] consult with impaired physicians and their f[illegible] cians recovered from disability could be unic[illegible] this effort. (APA and the district branches [illegible] leadership.)
4. Self-awareness experiences and mutual [illegible] to explore stresses of medical practice on fam[illegible] hance the family's effectiveness as *the* suppo[illegible]

The medical student and resident. Medic[illegible] training programs should be encouraged to

1. Improve students' stress-handling tech[illegible] crease awareness of the physician's vulnera[illegible] tional disturbance and of available help.
2. Provide readily available psychiatric c[illegible] treatment.
3. Teach doctors to ask for help.

Most of these suggestions are already in pl[illegible]

locations. However, only a comprehensive effort will overcome the social and emotional barriers that still separate the faltering physician from effective help (3). It has been reported in a western state that 25% of physicians whose fitness to practice has been questioned by the medical licensure board end as suicides. Attempts to secure public funding of programs to counteract such tragedies often are met with condescending variations on the theme "physician, heal thyself." Others may report more encouraging results, but I believe that if the troubled physician is to have a better fate than the proverbial shoemaker's child, it is clear that we will have to take care of ourselves. Material from the third national AMA conference on the impaired physician (Sept. 29–Oct. 1, 1978) should clarify how we are to do this.

Nonconfusional Paranoid Psychosis Secondary to Anticholinergics?

SIR: I read with interest the article "Levodopa-Induced Psychosis: A Kindling Phenomenon" by Charlene Moskovitz, M.D., Hamilton Moses III, M.D., and Harold L. Klawans, M.D. (June 1978 issue). In that article they noted that 6 out of 43 patients "exhibited psychiatric side effects while on anticholinergics and/or amantadine alone. These symptoms were not qualitatively different from those seen in patients on levodopa or combination therapy." As I have not previously read any report of a nonconfusional paranoid psychosis secondary to anticholinergics I would be very interested to know if one of their patients on anticholinergics alone did indeed develop such a condition.

DAVID P. MOORE, M.D.
Louisville, Ky.

Dr. Klawans Replies

SIR: I am afraid that Dr. Moore is correct and that our statement is somewhat ambiguous. What we observed in patients who were on anticholinergics or amantadine alone were hallucinations that were not in any way different from those seen in patients on levodopa alone. We, too, have not seen any report of a nonconfusional paranoid psychosis secondary to anticholinergics. The point we wished to make was merely that the hallucinogenic state brought on by anticholinergics appeared to be identical to that of hallucinogenic states brought on by dopaminergic agents.

Testosterone Levels and Women's Sexual Preference

SIR: I have received many inquiries regarding an article I wrote with D. Lynn Loriaux, M.D., Ph.D., and Thomas N. Chase, M.D., on "Plasma Testosterone in Homosexual and Heterosexual Women" (October 1977 issue). Colleagues have asked whether I concluded that homosexual women demonstrated testosterone "abnormalities" compared with heterosexual women.

I would like to emphasize that the testosterone ranges for the two groups of women (homosexual and heterosexual) overlapped considerably. In fact, only 5 homosexual women had testosterone measurements above the range for the heterosexual women. Furthermore, all testosterone measurements—for the homosexual as well as the heterosexual women—fell within the range considered normal for women who do not have endocrine problems. (The normal range of <100 mg/100 ml was determined by Hazelton Labs, Inc., a laboratory under contract with the National Institutes of Health to perform radioimmunoassays.) Therefore I would not conclude that homosexual women have abnormal testosterone measurements.

Persky and associates (1) recently demonstrated that high-normal baseline testosterone levels in heterosexual women—levels that were equivalent to the highest levels measured in our homosexual women—were significantly correlated with high self-rated gratification scores and the ability to form positive interpersonal relationships. It would be interesting to determine whether high-normal plasma testosterone levels in homosexual women are correlated with similar sexual, social, or interpersonal advantages.

Clinics, Private Practice, and National Health Insurance

SIR: Donald G. Langsley, M.D., ended his article on "Comparing Clinic and Private Practice of Psychiatry" (June 1978 issue) by saying, "It seems fair to conclude that . . . private psychiatric treatment can be successfully defended and financed." However, if I were a member of the United States Congress formulating plans for mental health care coverage under national health insurance (NHI), Dr. Langsley's article would lead me to believe instead that clinics such as the community mental health center (CHMC), in addition to providing services which are not available in the private sector, can and do provide treatment services identical to those provided by the private practitioner. I would conclude that the clinic system constitutes the preferable mental health care delivery system.

Whether it is true or not, legislators today are of the general opinion that the CMHC working in tandem with health maintenance organizations (HMOs) will best serve the mental health care needs of the nation, providing services at the lowest possible cost. In fact, under all NHI plans currently before the Congress, the role of the private practitioner of psychiatry is greatly restricted, especially in providing out-

patient treatment. (The most liberal plan allows only 20 "private" outpatient visits per year.)

I think Dr. Langsley misleads us when he implies that clinic and private psychiatric practice are roughly equivalent. Could he have reached his conclusions because the clinic psychiatrists he reports on were actually working in private clinics rather than in HMOs or CMHCs? I cannot find such a demarcation. Could it be that the "majority" he reports on are unrepresentative of clinic and private psychiatrists taken as a whole?

Dr. Langsley makes a mistake, I think, by not examining the functioning of the clinic as a whole, but rather isolating the function of the psychiatrist within the clinic. Clinic staffs as a whole engage in more supportive psychotherapy than private practitioners, many (but not all) of whom choose to focus their treatment on more in-depth, reconstructive psychotherapy. This, I think, is a major point distinguishing the private practitioner of psychiatry from the clinic practitioner (all breeds), especially in the CMHC. It is one definite reason why the private psychiatrist should be entitled to provide care under NHI, or rather why the patient should be entitled to receive care from him or her.

In connection with Dr. Langsley's article, I would like to make a few general comments about mental health care in the public and private sectors. Unfortunately, by their design public clinics (such as CMHCs) do not usually afford the patient the option of treatment by a psychiatrist. Even if they do, there is not much choice for the patient as to who his or her psychiatrist will be. We all know that this is a crucial choice because a patient can only work well with a psychiatrist with whom he or she can establish a strong rapport.

There is a strong case to be made to the effect that the individual patient is more likely to receive in-depth comprehensive treatment from the private practitioner of psychiatry. Public clinics are oriented toward treating the patient in a brief number of visits because they operate under broad economic pressures that really do not take into account length or depth of treatment. Consequently, a clinic's treatment goals may well differ from the patient's own treatment goals. By contrast, when a patient is treated by a psychiatrist in private practice, he or she is able to work with the psychiatrist until both feel that a "cure" or the optimum possible readjustment has been reattained (provided, of course, financial resources are available to support treatment such as this).

We do have statistics that bear out the differences between treatment the patient receives from a public clinic versus the private practitioner. The average number of visits per patient at the CMHC is only 5.3 (1) in comparison with an average of 46 treatment visits per year to psychiatrists in private practice (2). (Even though the median of the latter type of visits is much lower, 25 visits, we must acknowledge that there is a group of patients, not necessarily more sick, for whom in-depth treatment is likely to produce a better result in terms of overall adjustment.) We would all acknowledge that for the most part, only very superficial mental health care can be delivered when a patient is treated only five times. This leads to one assumption: namely that the CMHC—and mental health care within the public sector in general—is oriented toward resolution of patient crises. It would seem, on the other hand, that the private practitioner of psychiatry works with his patients not only to alleviate the acute presenting problem, but to enable the patient to change his behavior so that his crises do not repeat themselves ad infinitum. In the HMO, too, I think we shall find significant economic disincentives to the practice of such "private-style" open-ended psychotherapy, as well as limited cho[illegible] for the patient.

Unfortunately, the private practitioner of [illegible] not justify his existence under NHI unless [illegible] what he does is different, important, and [illegible] effective. Either that, or he can appeal to th[illegible] enterprise.

BOOK REVIEWS

The Other Generation Gap: The Middle-Aged and Their Aging Parents, *by Stephen Z. Cohen and Bruce Michael Gans. Chicago, Ill., Follett Publishing Co., 1978, 283 pp., $10.95.*

The generation gap discussed in this book presents a real and pressing problem for some families and bids fair to become equally important for many others as the life span for increased numbers of the elderly lengthens. More and more middle-aged families find themselves unprepared for the "real and often destructive feelings of anxiety and guilt because of their parents."

The main purpose of the book, the authors state, is to pull together materials and insights that might equip middle-aged sons and daughters to view their parents' physical, social, and emotional needs within the larger context of aging. To this end the authors have compiled information, guidelines, and suggested techniques from medical, psychological, and geriatric standpoints and present them from the point of view of the middle-aged individual. The authors rightly believe that understanding the dynamics of aging will help readers strike a better balance between their own needs and those of their parents. Wisely, they also believe that efforts should be made to encourage the parents' independent functioning and to postpone the time when they become a burden.

Unlike in Europe where the different generations of a family often live close to one another, generations in the United States frequently live apart. Thus, when the problems of elderly parents fall on the middle-aged they are often unprepared to handle them. Not infrequently they find themselves in a bind between trying to understand their own adolescent children on one hand and their elderly parents on the other.

A large number of the elderly fail to accept the physical changes taking place within them. However, these individuals are not as hard to care for as are those who magnify every bodily change and pester their children with their complaints. This can arouse resentment along with an urge to withdraw in the middle-aged children. In some cases children and parents have had poor interrelationships to begin with.

Although in some cultures the elderly are regarded as precious and their longevity enviable, in our culture the elderly are equated with uselessness. Women have lost their beauty and are not expected to be attractive. Elderly men are overly sensitive to the physical impression they make. The need to be noticed and desired is something many individuals never lose, no matter what their sex or age.

Disabilities, retirement, death of a spouse, and death of friends are all punishing blows for the elderly; often enough these events hint that death is not far off. Therefore, the elderly cling to a sense of continuity while their world steadily shrinks.

These facts require understanding on the part of their children, as do the elderly parents' methods of coping with their problems. By understanding these phenomena the offspring will learn how best to approach their parents when the need arises. The middle-aged children should also recognize that their parents' doctor is often regarded as the most important person in their lives and that they would do well to become acquainted with him. They might also take a long hard look at their own emotions over the years, considering the feelings they had about their parents and judging how much conflict might arise if they lived in close proximity to one another.

A genuine understanding of the inevitable changes happening to the aged is an essential element in the parent-child relationship. The habits of elderly parents are fixed and they are not going to change—in fact, they may become even more pronounced with age. The independent functioning of elderly parents should be prolonged by whatever combination of means necessary. The authors advise the formulation of a set of feasible limits to the child's direct involvement and determination as to whether his or her activities arise from a sincere desire to help or are motivated by feelings of guilt and obligation. They advise against martyrdom.

There is a discussion of nursing homes and the need for their inspection and for getting the advice of a skilled social worker about them before placing a parent in one. If a parent can live alone, independently, that is usually best. Most elderly individuals do not want to be a burden, and a quick reaction on the part of the son or daughter out of a sense of guilt and reawakened childhood worries can be destructive. The authors warn that rearranging one's own life because of such a reaction might well turn into a bitterly resented obligation. One must evaluate one's own qualifications and balance one's parents' needs with one's own while keeping the Biblical injunction regarding parents in mind.

F.J.B.

The Golden Cage: The Enigma of Anorexia Nervosa, *by Hilde Bruch, M.D. Cambridge, Mass., Harvard University Press, 1978, 150 pp., $8.95.*

Dr. Bruch describes anorexia nervosa as a disease that befalls the young, rich, and beautiful. She has made extensive contributions toward the understanding of this illness in the past and acknowledges that the disease is not really new. However, she suggests that its incidence has greatly increased in recent decades. The contention that the disease selectively afflicts the rich and beautiful, however, may be an artifact of patient selection rather than its true epidemiology.

The Golden Cage is a distillation of knowledge gleaned from many years of work with anorectic patients and their families. It addresses a wide audience, both lay and professional. Although it is only 150 pages long, its content and substance are substantial. The title evokes the imagery described by one of the patients, who saw herself as a sparrow in a golden cage, too plain and simple for the luxuries of her home but deprived of doing what she truly wanted to do.

Even though English is not her mother tongue, Dr. Bruch

has that rare capacity for beautifully and accurately conveying what she wants to say. In her characteristically incisive style she places into sharp focus the nature of the disease, its antecedents, the development of the illness, its psychological characteristics, and the process of treatment. Throughout the lively text are interlaced case vignettes and anecdotes. She integrates the best of both worlds: appreciation of the importance of physiological changes attending starvation and a thorough understanding of the psychodynamics underlying the psychological conflicts in the patient and operating within the family.

The book will be informative, educational, and helpful to anorectic patients and their families. It will aid them to understand better the disease and to evaluate the adequacy of their treatment. At the same time it will be of immense value not only to the beginning therapist but also to the experienced one. The last chapter is a masterful exposition of psychotherapeutic technique. Dr. Bruch states, "The task of psychotherapy in anorexia is to help a patient in her search for autonomy and self-directed identity by evoking an awareness of impulses, feelings, and needs that originate within her." The principles of treatment Dr. Bruch espouses have much broader implications and applications for disorders other than anorexia nervosa.

The Way Out Must Lead In: Life Histories in the Civil Rights Movement, *by William R. Beardslee, M.D. Atlanta, Ga., Emory University Center for Research in Social Change, 1977, 169 pp., no price listed (paper).*

This book is a significant contribution to psychiatry and to the history of the civil rights movement in the United States. Through a series of open-ended interviews with representative leaders in the struggle, Dr. Beardslee has recorded vignettes of personal commitment and involvement in a cause that are not easily understood in purely psychological terms.

All 11 interviews are presented with some editing, in vivid conversational style. This allows the reader to hear the stories in the interviewee's own words. The nuances of dialect and background are all there, capturing some of the flavor and beauty of the civil rights movement experience.

Of the 11 historians, 10 are black and one is a white minister. The author interviewed three black women whose roots are in the South. The seven black men are of varying ages, and have backgrounds in both the North and South. This small sample thus represents a spectrum of the leadership involved in the movement. While moving from one interview to the next the reader experiences a sense of the excitement and anticipation of personal drama. However, one wonders why the author gives fictitious names to all but three of the historians, since most of them are easily identifiable as leaders and public figures.

Dr. Beardslee's approach of interviewing leaders is probably the best way to capture the spirit of the movement in this short book. The historians are articulate and insightful. However, the reader must not forget that these individuals do not represent the typical civil rights worker. The workers Dr. Beardslee chose are those who made a long-term commitment, perhaps a lifetime commitment, to the cause of furthering human rights. They are the ones who stuck it out during the worst times. All experienced periods of profound personal stress but, nonetheless, remained in the struggle. In addition, the activists represented do not incl[ude those] either became disenchanted or whose spirit w[as broken] ing the days of violent and frustrating confr[ontations] racist southern authorities during the 1950s a[nd] civil rights workers dropped out either after a [summer] to two years. The group that is not represent[ed] given us a broader picture of the forces that [led] become involved in that historic movement. [Further,] was quite impressed with the author's caut[ious] the personal drives and ideologies that propell[ed] ers and reflected the spirituality and courage [that] them on the firing line.

What makes one stand up and continue to f[ight] under fear of imprisonment, violence, and ev[en] author realizes that such questions are ofte[n] not easily understood. Except for brief refe[rences] Erikson's theories of identity formation, [he] avoids a strictly psychiatric analysis of the r[eal] does not look for explanations in negative an[d] does he suggest that the workers were acting [out] suicidal impulses, or working through oed[ipal] Many will recall that civil rights workers w[ere] lyzed in this fashion by psychiatrists in the [1960]s.

Dr. Beardslee recognizes that the workers [experienced] ner psychological changes of great dimension[s. Much] change was a direct result of their involven[ent] workers in a just cause. People in the movem[ent] ing *with* others *for* others. This sense of co[mmunity] atmosphere of sacrifice and sharing was the s[trong] for most of the workers described in this b[ook. Most] already grounded in a strong religious spirit [now] hanced in a real human struggle to make all m[en] brothers and sisters on earth as well as in he[aven]. That activists actually brought about radical ch[ange] ca to take us one more step to the Promised L[and] the most sustaining factor in their ability to [persevere] ing on." Civil rights workers displayed a g[reat] tuitive insight when they spoke of being [on a] high."

In a closing chapter Dr. Beardslee provide[s an] analysis of the experience. Like his contemp[orary] ert Coles, he has not contented himself with [the] chair psychiatrist. He has gone into the [field] source—to learn a bit more about the sociops[ychology] heroic fighters of the civil rights movemen[t. How] nately and too quickly drifted into anonym[ity] will find this book educational as well as an [inspiration]. ly warding epic of human strength and struggl[e] the most important periods in American his[tory].

ALVIN F. POU[SSAINT, M.D.]
B[uffalo, N.Y.]

Manic-Depressive Illness: History of a Synd[rome], *ed[ited by] Edward A. Wolpert, M.D., Ph.D. New [York]. International Universities Press, 1977, 587 pp., $2[5].]*

According to his introduction, Wolpert [has] this volume "to present papers historically [significant] development of our understanding of . . . [manic-depressive] illness." To this end, he included the follow[ing] by Kraepelin, two by Abraham, and two by [Lewis] cally oriented papers by Katan, Jacobson, [Lehrman, Lo]tan, Fromm-Reichmann, and Cohen and ass[ociates]. papers by Cade, Schou, and Stallone and [Lange].

netic paper by Reich and associates; sleep research papers by Hartmann and Kupfer and associates; two "biosocial attempts at synthesis" by Schildkraut and Kety and by Akiskal and McKinney; and two papers on manic-depression in children by Anthony and Scott and by Feinstein and Wolpert. Ten of these 22 papers were originally published in the decade before 1977, so Wolpert was clearly relying heavily on his own prophetic skills in determining that they are of historical significance.

The criteria for inclusion were evidently diverse. Some of the papers are widely cited classics, familiar to most readers if not in their original form then from secondary sources. Some were probably included because they are typical of a genre, some because of the historical surveys they include. The quality of the papers is variable.

Reading the hundred pages of Kraepelin's writings included here gives one an awareness of why Kraepelin was so influential: his statement is lucid, comprehensive, and has a ring of authority to it. Although some passages consist of speculations that now seem implausible, other passages would be difficult to improve on in a contemporary text.

Reading both the 1912 and the 1924 papers by Abraham, one cannot help but be aware of his preoccupation with orthodoxy. Abraham seems at least as interested in whether his views converge with those of other analytic writers as in whether his views have clear clinical support. Reading next the familiar papers by Freud, one finds the kind of clarity of thought and expression noted in Kraepelin's writings, and one knows that Freud's dominance among early analytic thinkers was not due solely to his seniority in the club. Katan's paper, to a much greater degree even than Abraham's, seems addressed only to a very limited audience of the faithful. It seems almost to embody in caricature form the common weaknesses of analytic writings—treating constructs as if they were realities and inferences as if they were observations and assuming that dynamic elements deemed present in a disorder must have etiological import.

Jacobson's paper is immeasurably more comprehensible, perhaps in part because some acknowledgment is given to real life events, with a focus not so exclusively on patients' fantasies and the theoretical propositions of other analytic writers. Freeman's paper has some of the attributes of each of the two previous ones.

The remaining three dynamically oriented papers—Levitan's, Fromm-Reichmann's, and Cohen and associates'—are excellent, readable papers. The latter two are already classics, and I agree with Wolpert that Levitan's paper will (or should) become one; it has more fresh observations in it than most of the rest of the book put together.

Of the papers on biochemistry, genetics, and sleep research, only one—Cade's 1949 paper on lithium—is clearly of historical import. The rest seem merely typical of a genre of research report and not much more important than a myriad of similar papers. The best papers in the lot, those by Schou and by Schildkraut and Kety, are somewhat dated research reviews. I would prefer to have read current statements on the topics (lithium and biogenic amines, respectively). The paper on biogenic amines also lacks a focus on manic-depressive disorder.

Anthony and Scott's contribution on childhood manic-depressive psychosis is one of the few gems that made a careful reading of the book worthwhile. Its historical, systematizing approach make it the kind of paper I wish were available for adult manic-depressive disorder, in which case it would nearly obviate the present volume. The paper also provides a context in which the case report presented in the Feinstein and Wolpert paper can be seen to be of considerable import.

I cannot imagine a situation in which I would tell anyone that he or she ought to read Wolpert's book on manic-depression. A person claiming competence in psychopathology should be familiar with most of the issues raised in it, and students in any field should, from time to time, sample the early masters directly rather than relying solely on secondary sources. However, both of these goals can be met in ways that are simpler and less expensive than buying and reading this book. On the other hand, there are few papers in the book that I would say are a waste of time to read, and there are a few papers, in particular Levitan's and Anthony and Scott's, that even very well-read psychopathologists may find new and provocative.

PAUL H. BLANEY, PH.D.
Coral Gables, Fla.

A History of Aggression in Freud. Psychological Issues Monograph 39, *by Paul E. Stepansky. New York, N.Y., International Universities Press, 1977, 196 pp., $12.50.*

To trace and to understand the place of aggression in Freud's thinking is a difficult task given the complexities and turns which that thinking took. It is remarkable indeed that this history of Freud's views on aggression was originally formulated and drafted as a senior thesis by the author while he was an undergraduate at Princeton.

Stepansky approaches the problem from two points of view. The first is that of aggression as a metapsychological issue in psychoanalysis. The second is more hazardous: acknowledged speculations about the psychohistorical, psychobiographical, political, institutional, and personal reasons Freud might have had for his changing and often confusing positions on aggression.

Psychoanalysis as a therapy led Freud to formulate his earliest ideas about aggression. It was in his efforts to understand the hysterical and obsessional disorders that aggression had to be taken into account, but these earliest efforts were not fruitful. Eventually Freud's self-analysis and dreams about the deaths of parents and siblings as well as dreams that depicted aggressive wishes and acts for professional revenge had to be understood and explained. In "Three Essays on Sexuality" (1) aggression is depicted as a sadistic component of sexuality, but in *Jokes and Their Relation to the Unconscious* (2) aggression is given an instinctual status of its own. Stepansky holds that Freud then rejected the existence of an independent aggressive instinct because of his hostile relationship to Adler and because Adler presented a threat to psychoanalysis. Further, Stepansky repeatedly focuses on Freud's proposal of a death instinct. Few psychoanalysts will disagree that any clinical implications can be drawn from a biologically determined death instinct. More certain to stir disagreement are the suggestions that Freud's views about war were intended to avoid dealing with an innate, individual aggressive instinct, that he broke with Adler because Adler proposed an independent aggressive instinct first, and that Freud's own aggressive tendencies caused interference because of the anxiety and guilt they provoked.

Controversy about the place of aggression continues to the present day. Some contemporary psychoanalysts believe that aggression occurs in response to stimuli that evoke it. Other contemporary psychoanalysts consider it innate. Although I agree with the latter group, I would hesitate to ex-

trapolate in the way Stepansky does about the former. In some ways he joins Wittels (3, 4), Roazen (5), and others in weaving together psychoanalysis as theory and the person of its founder. This will almost certainly draw responses of the kind that Eissler (6) made to Roazen. That is to say, Stepansky's interpretation of the complex internal and external forces impinging on Freud will be challenged. His exposition of the vicissitudes of aggression in Freud's work is in a way separate from that interpretation and is a significant contribution.

Biochemistry of Mental Disorders: New Vistas, *edited by Earl Usdin and Arnold J. Mandell. New York, N.Y., Marcel Dekker, 1978, 268 pp., $29.50.*

This volume, the latest in the Modern Pharmacology-Toxicology series, reports the proceedings of the 1975 Intra-Science Foundation Symposium. At the meeting Dr. Seymour Kety was awarded the 1975 Intra-Science Foundation Gold Medal for his fundamental contributions to our understanding of the biochemistry of mental disease. Forty-four psychiatrists and neuropharmacologists presented their views, reviews, research, and speculations concerning new vistas in this area of research. This volume includes both historical perspectives of the early research in mental disease as well as data using such modern techniques as electron spin resonance in the study of monoamine oxidase. Unfortunately, the book is far from unique in the library of the neuropharmacologist, which currently contains many proceedings of similar symposia.

As in all such proceedings, the chapters vary greatly in their quality. The chapters by Drs. Kety and Felix are very entertaining and help put current research in mental disorders into perspective. Dr. Bloom's paper on the role of the electrophysiologist in the investigation of psychiatric disorders and the discussion that follows are excellent not only for their historic insights but also for Dr. Bloom's view of the complex electrophysiological properties of catecholamines. He demonstrates that norepinephrine cannot be classifed simply as inhibitory or excitatory on postsynaptic cells but, rather, that its synaptic effects depend on the simultaneous activity of various other pathways. Reviews by Drs. Bunney, Aghajanian, Goodwin, and Dement are short, concise summaries of the state of the art as it existed in 1975. Several other papers are less useful because the studies are very preliminary and the data are not statistically convincing. Furthermore, no new or innovative techniques [illegible] These chapters include the genetic study of Dr. [illegible] lithium study of Dr. Judd and associates, and [illegible] study of serotonin metabolites in psychotic p[illegible]ts.

It was disappointing to see no discussion [illegible] nonbiogenic amine transmitters in psychiatric [illegible] no data pertaining to the relationship of per[illegible] and endocrine abnormalities to mental disea[illegible] research on these topics has been done since 1[illegible] but other psychopharmacological volumes th[illegible] such a delay in publication contain this inform[illegible] probably represent a more rational investmen[illegible] ent publication.

ANNE B. YOU[illegible]
Am[illegible]

The Whipping Boy, *by Beth Holmes. New Yo[illegible] ard Marek, 1978, 458 pp., $10.00*

The author of *The Whipping Boy* describes [illegible] book about emotionally disturbed children:

> *The Whipping Boy* exposes one of the [illegible] most terrible secrets of our legislators, jud[illegible] yers. They have a problem they pretend [illegible] ist—because they don't know how to cope [illegible] problem is that more children are totally [illegible] parental emotional abuse than by physical [illegible]

Despite the fact that the book is really not [illegible] ally abused children but, rather, about a host [illegible] psychiatric issues, it is of interest to mental [illegible] and the lay public. *The Whipping Boy* is the [illegible] derline/psychotic boy and his seriously ill mo[illegible] It chronicles his symptomatology, his family [illegible] interaction, and their cross-country search [illegible] help. An astute clinician would say that the [illegible] toms were not consistent, the family patte[illegible] nomonic, and the diagnosis, prognosis, and t[illegible] offered by the child psychiatrists questi[illegible] theless, despite its clinical inaccuracies, the [illegible] ping, and it does reveal some of the problem[illegible] sion. That is to say, for seriously disturbed [illegible] diagnose illness and recommend treatment [illegible] quate treatment facilities, carefully staffed w[illegible] able clinicians, are not always available or are [illegible]

Unfortunately, despite the clinical conditio[illegible] onist (Timmy), which is ambiguously presente[illegible] ters that surround him—his mother, his fathe[illegible] brother, the child therapists—are either good [illegible] such, lack credibility. An in-depth look at [illegible] environment is really an exercise in putting [illegible] ther rather than mother, and it is clear, at l[illegible] the protagonist is a victim of "poppism."

Despite its many flaws—in characterizat[illegible] and literary style—I found the novel gripping [illegible] a detective story with psychological insights [illegible] with the clinical accuracy and richness of no[illegible] (1) or *I Never Promised You a Rose Garden*[illegible]

Student's Rorschach Manual: An Introduction to Administering, Scoring, and Interpreting Rorschach's Psychodiagnostic Inkblot Test, revised ed., *by Robert M. Allen, Ph.D. New York, N.Y., International Universities Press, 1978, 353 pp., $15.00.*

Described as "an expanded and updated edition" of a book first published in 1966, this revised volume totals 30 chapters, 3 of which are new. Two of the new chapters pertain to perception theories and the teaching of projective techniques in universities and practicum agencies. The third new chapter briefly discusses the Rorschach as a measure of a child's cognitive development in lieu of formal IQ testing. There is also a useful gossary of Rorschach terms and symbols and several pages on audiorecording of the Rorschach that are not found in the earlier book. Unfortunately the current text's reference section includes a mere handful of Rorschach literature citations published after the 1966 manual, omitting such comparatively recent books as Aronow and Reznikoff's (1), Exner's (2), and Goldfried and associates' (3). Thus, the present volume is not substantially different from its 1966 predecessor.

Allen gears his text to teaching the basics of administering, scoring, tabulating, and interpreting the Rorschach. He has largely succeeded in writing an eminently readable and comprehensible manual for the Rorschach neophyte. The book is organizationally sound, with the scoring and interpretive elements of the various Rorschach location areas and determinants interwoven in a meaningful fashion. The author uses illustrative material very effectively, even including a diagram of the best seating arrangements for the administration of the test. His sample protocols are well chosen and presented with clarity. Very appropriately, Allen has elected to include a "normal" case.

Even allowing for the fact that the book is intended as an introductory text, however, Allen's discussion of Rorschach content is too narrow in scope. No mention is made of the many content scales found in the literature, some of which are highly encouraging with respect to reliability and validity factors. Notable is Schafer's personality themes (4) and Elizur's anxiety scale (5). On the other hand, Allen's treatment of the content components of each of the 10 Rorschach cards, discussed individually, is very informative yet properly circumspect so as not to stimulate flights of speculative overinterpretation.

In sum, this text is, for the most part, a very reasonable choice for an elementary Rorschach course, both for teaching the fundamentals of the technique and underlining the need for the beginner to seek more advanced training.

Short Forms of the MMPI, *by Thomas R. Faschingbauer and Charles S. Newmark. Lexington, Mass., Lexington Books (D.C. Heath and Co.), 1978, 179 pp., $15.00.*

It is universally agreed that a short form of the MMPI is preferable to a full-length MMPI only when a full-length MMPI cannot be obtained. A full-length MMPI involves endorsing 550 statements as either true of oneself or false. This is a time-consuming task that can also be tedious; consequently, the use of the full-length test is often impractical in many research designs, especially ones that require multiple administrations of the test. In clinical settings the full-length test may not be obtained without a certain amount of stamina and willingness to cooperate on the part of the person taking the test.

Short forms of the MMPI have been developed primarily by finding the fewest items necessary either to yield a profile that matches the profile generated by the full-length test or to yield a profile from which statements about the person may be made that are useful and accurate when compared with some nontest criterion. The short forms were developed primarily among three populations: college students, psychiatric inpatients, and psychiatric outpatients. The clinical usefulness of a short form would be primarily in cases where patients are unable or unwilling to complete a full-length MMPI.

Short Forms of the MMPI renders a thorough rundown of the construction and the strengths and weaknesses of five well-developed short forms plus information on two efforts that extend or improve on a short form. The authors compare the short forms in a variety of populations and also discuss critical issues involved in the use of new forms of the MMPI that may risk the integrity of the original time-honored test. The short forms given the most attention are Kincannon's 71-item Mini-Multi (1), Dean's Midi-Multi (2), Hugo's short form (3), Faschingbauer's Abbreviated MMPI (4), and Overall and Gomez-Mont's MMPI-168 (5), which uses only the first 168 items of the standard MMPI. Two abbreviated MMPIs that are also described in this book were developed independently to improve on the Mini-Multi. These were developed by McLachlan (6) and Spera and Robertson (7); both are titled Maxi-Multi.

A clinician who respects the MMPI and is experienced in reading MMPI profiles appreciates the abundance of information it provides. Well-developed short forms are welcome when a full-length MMPI may not be obtained. However, each of these short forms is going to have to make it on its own. The short form is a related but separate test from the original. This book is a thorough guide to short forms and one would do well to read it before choosing a short form and before using any short form at all.

Assessing Personality Through Tree Drawings, *by Karen Bolander. New York, N.Y., Basic Books, 1977, 412 pp., $20.00*

Attitudes toward projective testing always underscore vividly the regrettable divorce between clinicians and researchers. That books on assessing personality can be of interest exclusively to one group or the other is a sad reminder that the two worlds remain dissociated. In the case of *Assessing Personality Through Tree Drawings*, most clinicians will accept the idea that personality, too complex and subtle for scientific or statistical methods, can be revealed in a drawing of a tree. Personality researchers like myself will be skeptical, but the book is not written for researchers.

On the basis of her experience collecting and studying the tree drawings of thousands of people, Dr. Bolander concentrates her presentation on how to interpret tree pictures for clues and insights concerning an individual's experiential history and psychological state. Intended to instruct the novice arboritor, the text is written clearly, and the lengthy method section is organized logically. The basic information necessary to interpret central themes in a drawing is given in four key schematic figures. These schemata define the meaning of the space in which the tree is drawn and the meaning of the various tree components. The crown represents mental life, the trunk represents emotional life, and the roots represent instinctual life. Details toward the left side are feminine, details toward the right are masculine. Specific content like branches, leaves, shading, groundline, knotholes, and type of tree are described separately and allow increasingly detailed inferences. Figures and illustrations of all of these elements, individually and in combination, are plentiful.

The basic schemata and many of the interpretive guidelines are intuitively appealing—overemphasized root systems indicate being firmly rooted in reality, dead trees often indicate the feeling of complete victimization by external forces, knotholes and scars indicate traumatic experiences. The problem here, as with other similar interpretive systems, is determining whether there is any usefulness to the schemata beyond their intuitive appeal. Moreover, even if the basic schemata are accepted, when do interpretive guidelines and generalizations apply to a particular case? Unfortunately, despite the wealth of data available to the author, very little evidence is presented to substantiate any of the method. The book is written with the understanding that the answers to these questions lie ultimately in each user's own evaluation of the method. This position is not unreasonable, given the current state of clinical assessment, but it again illustrates the wide gap between clinical and research perspectives.

It would be unfair to judge this work against [illegible] lems of clinical psychology, psychiatry, and personality assessment. This is a perfectly appropriate and [illegible] for clinician users of projective tests and for [illegible] especially. Used in conjunction with other sources of information about an individual, as the author recommends, many practitioners will find this interpretive system helpful.

Despite the skepticism and the critics, projective approaches to personality assessment survive. [illegible] human personality will always tolerate and test attempts at understanding a little more.

Bet[illegible]

Interpreting Psychological Test Data, Vol. I, *by [illegible] bert, Ph.D. New York, N.Y., Van Nostrand [illegible] 1978, 237 pp., $15.95.*

This is the first of two volumes of this text, [illegible] now in preparation. The primary purpose of both [illegible] to associate personality and behavior with [illegible] tained from the four tests that are most often used [illegible] porary psychodiagnostic evaluation: the Bender Gestalt Test, the Human Figure Drawing Test, the Wechsler Adult Intelligence Scale (WAIS), and Rorschach Psychodiagnostic Inkblot Test.

This volume "abstracts and synthesizes [illegible] books regarded as standard references in the [illegible] pects of behavior which are assumed to be related [illegible] psychological test productions" (p. vii). The "[illegible] erences" abstracted are certainly authoritative [illegible] the tests included. Several equally applicable [illegible] reference sources are excluded, however. This [illegible] is readily admitted by the author: "For the [illegible] foundations provided by the cited references [illegible] suffice" (p. vii). Unfortunately, the limitations [illegible] volume will apply to the forthcoming second volume. The author promises that volume II "will bring together in summary form the diagnostic syndrome of behavioral attributes suggested by test responses" (p. ix).

If, as the author states, one of his future objectives is to expand the present volume (p. vii), the contemporary usefulness of the second volume faces limitations similar to obsolescence. Volume II will refer to diagnostic syndromes based on criteria used in the first and second editions of *DSM III*. The fact that the second edition of *DSM* (1) is currently being revised (2) adds further to the obsolescence of these volumes. Another example of this dilemma is noted in the chapter in which the author devotes approximately 50 pages of pagination to the interest content of the Rorschach. The entire text on interest content of this test has been recently published (3).

Another major critical issue is the exclusion of [illegible] sources from texts that would assure adequate [illegible] sample of data for specific age groups, especially [illegible] This particularly applies to texts on the Bender-Gestalt test. Koppitz' work (4), which is entirely devoted to normative data for children in different age groups, is not [illegible] From a contemporary point of view, the Bender is extremely useful in learning disorders and certain [illegible] tion. The author also fails to include the Wechsler Intelligence Scale for Children (WISC-Revised) [illegible]

of only the WAIS limits the use of this reference source for people who work with children.

Almost two-thirds of this volume is devoted to the Rorschach test. This is justifiable in light of the frequency of its use in psychodiagnostic procedures. However, half of this portion of the book concerns interest content. Since volume II purportedly will relate these data to diagnostic nomenclature, more objective and normative Rorschach data will be needed. Likewise, the author's effort to equate the several Rorschach scoring systems (p. vii) has already been accomplished in another text (5).

The author's question of "whether the present volume fulfills a useful role in the profession" (p. vii) is certainly open-ended. Perhaps the introduction is most pertinent in expressing the author's awareness of the critical theoretical issues that limit the valid and reliable usefulness of this volume. One purpose of this text—"to provide a rapid useful reference source" (p. vii)—has been accomplished. However, the scope of the sources used limits even this.

Depression: Biology, Psychodynamics, and Treatment, *edited by Jonathan O. Cole, Alan F. Schatzberg, and Shervert H. Frazier. New York, N.Y., Plenum Press, 1978, 242 pp., $22.50.*

This book consists largely of material presented at a one-day symposium on depression held in March 1976. No doubt those who attended that symposium were favorably impressed with the relative newness of what the speakers said. A more than two-year delay in the publication of this material has aged it, compelling me to assert that now these pages contain little that is new or helpful for the basic scientist or the clinician. In fact, a good portion of this volume has been published in either journals or books, including the proceedings of other symposia on depression. Furthermore, the book has many of the deficiencies of multi-authored symposium proceedings. It is neither comprehensive nor an in-depth coverage of the subject matter; therefore, it is very difficult to decide for whom this book should be recommended. It is already outdated. It is a historical record of the views of some American experts on various aspects of depression in 1976. Its contents do not justify purchase by students of psychiatry, and it certainly is not designed for those working in the field of depression.

The Child Protection Team Handbook: A Multidisciplinary Approach to Managing Child Abuse and Neglect, *edited by Barton D. Schmitt, New York, N.Y., Garland STPM Press, 1978, 407 pp., $24.50.*

In their scrupulous effort to avoid omitting essential data, most handbooks and compendia, including this one, tend to exaggerate the value of vigorous adherence to the practices and procedures the authors have found comfortable. If and when such handbooks become the standard, to take unsanctioned shortcuts is deemed slipshod, to be casual is thought uncaring, and to vary from the procedures may be malpractice. When the interdisciplinary approach is overemphasized, as it is in this handbook, the procedures outlined become cumbersome and time-consuming. The careful delineation of the role of the different disciplines, respectful as it is to the contribution that each discipline can make, becomes role padding when these different perspectives add little new dimension to the solution of problems. Similar insights derived from different sources are no less repetitious than when they come from a single source. What such role clarification does for the child-abusing parent is conjectural. On the one hand, it may be flattering to have so many important individuals preoccupied with him or her. On the other hand, the help of so many specialists focused on his or her many difficulties may make the parent feel like an insignificant figure in a bureaucratic maze.

Some of the statements in this text are more likely to raise eyebrows than receive enthusiastic affirmation. That 80% of these parents are treatable and that most of them love their children are questionable theses, no matter how loosely we define treatment or love. The necessity of parenting does not make parenting an automatic virtue. If child-abusers could accept parenthood as neither virtue nor vice, they might be less likely to exaggerate the investment parenthood entails with less fruitless anxiety about their lack of preparation for parental responsibilities. The hostility of many of these parents to their children derives in part from their ignorance and unsophistication. Since many of them are unprepared for the struggles and complexities of interpersonal relationships, it is logical that they see their children as their equals and hence willful opponents to their wills. In a sense, child and parents are both in the "flyweight" class. To make "heavyweights" of these parents, to reduce their arrogance and stubbornness, requires not only instruction in childrearing but some understanding of interpersonal dynamics.

The authors have made a laudable and conscientious effort to develop a team approach to the diagnosis and treatment of child abuse. They have collected and collated much of the technical information necessary for the child abuse teams now proliferating in this country. At times they overemphasize tact, which becomes indistinguishable from timidity. The emphasis on tact undoubtedly reflects the authors' obvious respect for their colleages and their patients.

IRVING MARKOWITZ, M.D.
Orange, N.J.

Ecologic-Biochemical Approaches to Treatment of Delinquents and Criminals, *edited by Leonard J. Hippchen, Ph.D. New York, N.Y., Van Nostrand Reinhold Co., 1978, 392 pp., $16.95.*

No book that recognizes a biochemical contribution to antisocial behavior can be all bad—at least so I thought until

I read *Ecologic-Biochemical Approaches to Treatment of Delinquents and Criminals*. Of course, until then I was not aware that corporal and capital punishment were biochemical treatments.

This book consists of 20 chapters written by individuals from a variety of disciplines, including a "licensed medical hypnotist," an optometrist, and an "orthomolecular family physician." Topics range from the etiology of learning disabilities ("children with learning and behavior disorders are vitamin B_3-B_6 dependents. A second major cause of perceptual changes is food allergies" [p. 14]) to the treatment of penitentiary inmates ("In my opinion we need capital and corporal punishment more now than ever before, because more people are getting into this mindless state where life means nothing" [p. 277]). The author of these words clearly felt that "life means nothing."

Topics also include the orthomolecular treatment of antisocial behavior ("The three most common forms of criminal malnutrition are . . . the vitamin B dependencies, . . . the saccharine diseases [the relative hypoglycemias], . . . the cerebral allergies" [p. 4]) and the effect of tinted sunglasses on behavior ("Three students constantly wore 'hot-pink' sunglasses, and a check on faculty ratings indicated that these same students were also considered to be the most psychologically disturbed students in the college" [p. 109]). The obvious fact that the choice of a particular style rather than its effect on behavior might be associated with maladaptation is not appreciated. Most unfortunate, in light of the emphasis in this book on so-called cerebral allergies, is the failure of contributors to distinguish between allergic and toxic reactions to substances. For example, one of the authors cites the following as an example of neuroallergy: "Befuddled thinking or an acute episode of mental illness may occur upon exposure to petroleum fumes, carbon tetrachloride, the fumes of a gas range, or the odor of a magic marker" (p. 239). This is not allergy!

A critical reader of this book might wrongly discount the possible contribution of malnutrition to maladaptation. There are reputable investigators in the field of nutrition and behavior whose work, although not included in this book, deserves attention. Unfortunately, the contributions of Cravioto and Delecardi, Wurtman, Pollitt, and others are by and large ignored.

Unfortunately, claims in this book are so grandiose (e.g., "The evidence suggests that recidivism rates among prison populations could be reduced 25–50% with the addition of orthomolecular treatment" [p. 16]), any kernels of truth this book might contain are lost. The association of malnutrition and maladaptation is made to look ridiculous rather than worthy of further scientific investigation.

It would seem that faith rather than scientific knowledge guided the pens of the authors. Perhaps this book would have been reviewed more appropriately under the category of religion or science fiction.

DOROTHY OTNOW LEWIS, M.D.
New Haven, Conn.

John of God: His Place in the History of Psychiatry and Medicine, *by Ruben D. Rumbaut, M.D. Miami, Fla., Ediciones Universal, 1978, 70 pp., $4.00 (paper).*

The saints of all religious or spiritual traditions are interesting, not only in theological or cultural terms but also in psychological—one might also say psychiatric—terms. Juan Ciudad Duarte, who became known to history as Juan de Dios, is certainly no exception. His story is told in these pages simply and sparely: his birth to a poor Portuguese family, his running away from home with an itinerant clergyman at the age of eight, his subsequent adventures as a Moorish soldier, his return to his home years later to find the household in grief and tragedy precipitated by his departure, the subsequent misfortunes leading him to increasingly desperate straits, and, finally, the crucial conversion at the hands of Juan de Avila, the famous Apostle of Andalusia. Hearing Avila's fiery sermon apparently served as a cathartic experience, plunging Juan into a psychotic episode that appeared predominantly depressive in character.

The second part of the story starts with the post-conversion transformation of Juan Ciudad Duarte into Juan de Dios. Dr. Rumbaut then provides an account of Juan de Dios' saintly works and the founding of the distinguished Order of the Hospitallers of St. John of God and their worldwide work of caring for the sick, particularly the mentally ill and neurologically afflicted.

The story is well told and worth the retelling. There are certain interesting correspondences with the life of Juan's contemporary, Inigo de Loyola, who became known to history as Ignatius of Loyola, the founder of the Society of Jesus and the architect of the Counterreformation. Ignatius was born about the same time as Juan and served as an officer in the Spanish army. In fact, he was one of the garrison, in which Juan de Dios is said to have been a foot soldier. One wonders if these two men might have crossed each other's paths. In any case, Ignatius also had his trauma, his psychotic transformation, and he emerged from this soul-wrenching experience in Manresa with a new spiritual identity.

Such marvels of the human spirit excite the greatest imagination of the psychologically minded, but the present work offers us little more than a simple recounting of the events. There is little in the retelling that allows a distinguish between hagiographical mythology and authentic biography. There is no attempt to scrutinize or understand the psychological journey of this fascinating man. Moreover, the somewhat innocent suggestion that the famous Apostle served Juan de Dios in somewhat the role of a psychotherapist hardly matches the details of the account to the effects of the apostle's sermon on the distraught and tormented Juan. Anyone who undertakes to read this delightful account (the book is a bilingual edition printed in English and Spanish so that the whole story is told in less than 30 pages) will find in it a memorial to one of the great saints. However, if one looks here for any deeper understanding, any exploration of the dark continent of human psychology and spiritual experience, or even any attempt to illuminate the unique conversion experience of Juan de Dios, he will seek in vain.

W.W. MEISSNER, S.J., M.D.
Cambridge, Mass.

Mothers, Fathers, and Children: Explorations into the Formation of Character in the First Seven Years, *by [illegible] and Sidney Axelrad, with Ethel Horn, Marshall Lebovich, and Marvin Taylor. New York, N.Y., International Universities Press, 1978, 659 pp., $27.50.*

This book is a follow-up and expansion of an earlier one, titled *Anxiety and Ego Formation in Infancy* (1[illegible]

the authors reported a study of 131 mothers and their infants during the first year of life. For various reasons, the authors decided to follow 127 of the mothers and their children from the original study. Their intent was to determine whether the original patterns of mother-infant interactions continued relatively unchanged or varied during the ensuing years until the onset of latency. The authors are psychoanalytically oriented, and they felt that direct interviews with mothers and observations of children could contribute to our knowledge beyond the analytic process.

The book begins with an overview of the earlier study. Part one goes into detail about the methods used in that study. The mothers could have been divided into at least seven subgroups but, for statistical reasons, were separated into two types, A and B. The type A mothers were good parents who provided consistent emotional nurturance and support to their infants into the later years of childhood. Type B mothers were lacking in many of the ingredients of what one might consider good motherhood. The authors are quick to state that this does not separate the A and B mothers into good and bad, but the B mothers had more difficulty in adapting to the maternal role and were overprotective, underprotective, defensive, disinterested, or showed a variety of other patterns not conducive to good ego and personality development in their infants and children.

After their explanation of the method used, the authors present nine case reports of mothers and their infants. Part two, The Longitudinal Study: Mothers and Children, deals primarily with the follow-up of the original group of infants. The research group found that the children of type A mothers were better adjusted both at home and at school and had more adequate personality development than did the children of type B mothers. With the exception of more age-appropriate drawings in the A group, many of the four- and five-year-old youngsters in both groups gave similar impressions to the researchers at the height of the oedipal period. The group A children subsequently reassumed more normal overt development than did the group B children.

The study seems to indicate that some assumptions about changeability in parent or child are not necessarily valid: the concept that parental adequacy depends on the ability to shift from one to another type of identification with the child when the youngster enters a new developmental phase, the idea that insufficient or inappropriate parental responses during one phase of growth can be made up for in a subsequent period because of the child's resilience, the idea that a "good fit" between mother and child is important not only to their ongoing relationship but the child's progress. Although the authors agree that all of these points are of importance, they may not be quite so important as has been believed. In the summary of this portion of the book, the authors say,

> It is within the child's capacity very gradually to form a post-ambivalent connection to the parents and through them to more distant objects; to integrate the early affective bonds with motor, cognitive and language development— . . . to build an intact body ego and broaden capacities for gratifying experiences with a whole world of objects.

Part three, Fathers and Children, begins with a chapter on variations in paternal behavior and attitudes and then presents in some detail 10 case reports of mothers, fathers, and children. As with the preceding portion of the book, the cases are divided between parents who are more adequate and those who are less so.

This book is a report of a time-consuming study of prelatent children and their parents. The authors rightfully point out several times that it has some scientific flaws in methodology; nevertheless, it is basically a useful book. Perhaps it could have been written without such detailed case histories, but omissions might have left the reader in some doubt as to how the results were obtained. The basic constitution of the infant is taken into account as one possible variant among others, such as trauma resulting from repeated hospitalizations.

If one were to be critical of the case illustrations, such criticism might have to do with the omission of a study of why these couples did or did not plan their families. Although some attention is paid to the ages of the siblings and the ordinal position of the subject children, the authors do not seem to have asked the simple question, "What size family do you plan?" There also seems to have been a timidity on the part of the researchers to offer more active guidance to the parents. Perhaps this was not one of their intents, but it would seem appropriate in a study of this kind to know about family planning or the lack of it and about the communication between mother and father in regard to it. One would like to know whether active intervention of a preventive type could have been useful; however, since all of these parents were volunteers and could have refused to participate in the study at any time, the authors are to be congratulated for keeping so many involved.

The main and important thrust of this book remains clear: interaction between mother and infant in the first year of life is basic to future character and personality formation. Equally important is the fact that the personalities of the mothers and fathers continue along the same lines as were drawn in the first year of life. The book is to be recommended to anyone working with infants and children—child and general psychiatrists, psychologists, social and public health workers, nurses, and others in related fields.

Psychoanalysis and the History of the Individual, *by Hans W. Loewald, M.D. New Haven, Conn., Yale University Press, 1978, 77 pp., $7.95.*

This book is an edited version of the Freud-Kanzer lectures given at Yale University by Dr. Loewald. The author tackles such difficult and knotty psychoanalytic problems as morality, transference love, and religion. He notes that most analysts have continued in Freud's tradition and, as a result, are not comfortable exploring morality, love as opposed to sexuality, and religion.

Toward the end of the book, the author remarks that these lectures gave him an opportunity to say things he has had on his mind for a long time. This honest reevaluation of accepted ideas is reminiscent of Foulks (1), Grotjahn (2), and Mandell (3). The presentation is graceful and easily read. It is a disciplined but fanciful flight of imagination and intellect, a presentation of ideas rather than personal feelings and reactions. In this respect Loewald differs slightly from Foulks, Grotjahn, and Mandell. Loewald's overall approach seems

detached, objective, and free-flowing. At first I thought he was a philosopher. He is an analyst, but he seems to be at that point in life when men and women try to objectively evaluate themselves, their lives, and their professions.

Essentially, Loewald concludes that man must accept his id. This is the essence of morality. Such acceptance does not mean burying guilt or creating "fancy sublimations" because these things cannot be done. The id must be acknowledged as a part of oneself. Its manifestations cannot be blamed on, nor are they the responsibility of, society, God, parents, or anything else. Man is ultimately responsible. His moral task is to bring the id into the more lucid levels of mature thinking. The task is not to give up, deplore, undo, or deny it. It must be seen, understood, accepted, and worked on.

Transference and transference love, if analytically interpreted and worked through, should allow the patient a free, fanciful, libidinal, symbol-forming relationship among his id, ego, and superego as well as between himself or herself and object representations.

Dr. Loewald is impatient with most analysts' overly simplistic views of religion. He blames this on Freud's discomfort with religion. Neither Freud nor subsequent analysts seriously tackled this question. Loewald notes the similarity between sexual and religious ecstasy and the extreme vagueness conveyed by the term "sublimation." Religious experience and religious myths are important expressions of unconscious mentation. They are not just dependency, magical thinking, denial, or other defenses. Currently, religious feelings are more deeply repressed than was Victorian sexuality, and they are therefore more deserving of analytic attention.

This brief summary does not convey how the book forces one to think about issues not yet adequately explored by psychoanalysis. The reminder is subtly disturbing. I recommend the book to all psychoanalysts and to those psychiatrists with special philosophical and metapsychological interests.

Crisis Intervention As Psychotherapy, *by Charles Patrick Ewing. New York, N.Y., Oxford University Press, 1978, 125 pp., $7.95; $3.50 (paper).*

Crisis intervention is quite widely believed to be a good thing—ubiquitous as a term but not necessarily as a recognizable practice. One wonders whether part of its success might be due to its amorphous adaptability. It has become, for some, one of those vague vogue words (such as "family," "hotline," "access," "community," and "counseling") which one can add to the description of nearly any clinical or teaching program, like monosodium glutamate, to spice it up and make the flavor more acceptable without actually altering the contents. "There is a lot of it about," as one says during influenza epidemics, but one is less than clear exactly what it is.

Dr. Ewing's book covers quite a lot of territory relatively superficially, at the level of an extended review article, without really getting its teeth into the subject as one might have hoped. He presents a definition of crisis intervention that is a paraphrase of the popular definition of psychotherapy, adding only that its techniques are "derived from the established principles of crisis theory." Yet nowhere does one get any clear idea of any principle, practice, or technique that is unique to crisis intervention. It is never clear what distinguishes crisis intervention from any other variety of short-term psychotherapy. Indeed, there is a very loud silence on this point in the book. There is no mention at all of the highly relevant allied work on short-term and brief psychotherapy, and the work of Sifneos and Malan seems studiously ignored. This greatly reduces the clarity of the book's attempt to place crisis intervention in the general field of psychotherapy.

Ewing starts by describing basic crisis intervention theory, which seems a rather fragile foundation for what is to be built on it and claimed for it and somewhat lacking in validation. He describes some general principles of clinical practice (in no way distinct from other short-term therapies) and some current uses of crisis intervention in child and family therapy as well as with special client groups. There is a short review of some studies evaluating such programs, some thoughts on possible future developments, and a suggested model for clinical practice.

One chapter discusses the selection of appropriate clients, and is, probably appropriately, uncertain of criteria. There is a suggestion that crisis intervention may be better suited to clients of lower socioeconomic status than some other psychotherapeutic modalities. Otherwise the usual suspicion that the ideal client for any therapy is someone who is not too sick, only recently disturbed, highly motivated, and likely to do equally well if given macrame lessons applies. Comments like "Crisis theory . . . presupposes that crises are self-limiting and last for only a period of weeks" suggest either naïve theory or special pleading by choosing the crises likely to respond well to any intervention, while ignoring chronic crisis states or crises so overwhelming that they last for more than a few weeks. This is also in conflict with a good deal of high quality work studying crises like bereavement, which, although undoubtedly crises, are very rarely if ever resolved within weeks or even months, unless one is very easily satisfied with superficial criteria for "resolution."

The final disappointment about this book is the lack of a really critical approach to the issues raised. It will be comforting for those already convinced of the importance of crisis intervention techniques. Those who still wait to be convinced that there is a substantive and substantiated theoretical background and a distinctive and effective clinical methodology in crisis intervention are still waiting.

MICHAEL A. SIMPSON, M.D.
London England

This Month's Reviewers

ALEXANDER R. LUCAS, M.D., is Professor in Psychiatry, Mayo Medical School, and Head of the Section on Child and Adolescent Psychiatry, Mayo Clinic, Rochester, Minn.

ALVIN F. POUSSAINT, M.D., is Associate Professor of Psychiatry and Associate Dean for Student Affairs, Harvard Medical School, Boston, Mass.

PAUL H. BLANEY, PH.D., is Associate Professor of Psychology, University of Miami, Coral Gables, Fla.

JACOB SWARTZ, M.D., is Professor of Psychiatry, Boston University School of Medicine, and Training and Supervising Analyst, Boston Psychoanalytic Institute, Boston, Mass.

ANNE B. YOUNG, M.D., PH.D., is Assistant Professor of Neurology, University of Michigan, Ann Arbor, Mich.

ELISSA P. BENEDEK, M.D., is Director of Training, Center for Forensic Psychiatry, and Clinical Associate Professor, University of Michigan Medical School, Ann Arbor, Mich.

MARVIN REZNIKOFF, PH.D., is Professor and Director of Clinical Training, Department of Psychology, Fordham University, Bronx, N.Y.

DAVID F. BERRY, PH.D., is a Clinical Psychologist in private practice in West Hartford, Conn.

RICHARD J. HAIER, PH.D., is Staff Fellow, Laboratory of Psychology and Psychopathology, National Institute of Mental Health, Bethesda, Md.

H. BARRY MOLISH, PH.D., is Chief, Psychology Section, Department of Medicine, Texas Children's Hospital, and Associate Professor of Pediatrics (Psychology) and Psychiatry (Psychology), Baylor College of Medicine, Houston, Tex.

FRANK J. AYD, JR., M.D., is Editor, International Drug Therapy Newsletter, Baltimore, Md.

IRVING MARKOWITZ, M.D., is Medical Director, Family Service and Child Guidance Center of the Oranges, Maplewood, and Millburn, Orange, N.J.

DOROTHY OTNOW LEWIS, M.D., is Associate Clinical Professor of Psychiatry, Yale University Child Study Center, New Haven, Conn.

W.W. MEISSNER, S.J., M.D., is Associate Clinical Professor of Psychiatry, Harvard Medical School, Boston, Mass.

STUART M. FINCH, M.D., is Lecturer, University of Arizona College of Medicine, Tucson, Ariz.

FRANK M. KLINE, M.D., is Chief of the Psychiatry Service, Veterans Administration Hospital, Long Beach, Calif., and Vice-Chairman, Department of Psychiatry, University of California, Irvine, Calif.

MICHAEL A. SIMPSON, M.D., is Senior Lecturer in Psychiatry and in Medicine and Senior Research Fellow in Liaison Psychiatry, London University, Royal Free Hospital School of Medicine, London, England.

Books Received

This listing acknowledges the receipt of recent books. Books of particular interest to the readers of this journal will be reviewed as space permits, and copies of the reviews will be sent to the publishers. Books cannot be returned to the publishers.

The Mental Health Almanac, *edited by Robert D. Allen and Marsha K. Cartier. New York, N.Y., Garland STPM Press, 1978, 403 pp., $17.50.*

The Child in His Family, Vol. 5: Children and Their Parents in a Changing World, *edited by E. James Anthony, M.D., and Colette Chiland, M.D., Ph.D. New York, N.Y., John Wiley & Sons, 1978, 440 pp., $23.95.*

Bioethics and Human Rights, *edited by Elsie L. Bandman, R.N., Ed.D., and Bertram Bandman, Ph.D. Boston, Mass., Little, Brown and Co., 1978, 366 pp., $9.95 (paper).*

Foundations' Fund Fellowships for Sabbatical Research in Psychiatry and Its Basic Sciences

The Foundations' Fund for Research in Psychiatry announces a limited program of support for scholars on sabbatical leave in order to further their research and contribute to the knowledge of psychiatric diagnosis, treatment, and prevention. The sabbatical must be spent away from the home institution at an internationally recognized institution.

Applications are open to distinguished and creative investigators with demonstrated research contributions in the field who hold full-time positions in professional schools and graduate departments of universities or equivalent institutes of research. Applicants must be U.S. or Canadian citizens or permanent residents of the U.S. or Canada.

The deadline for receipt of applications is May 1 of the year preceding the proposed sabbatical.

Information may be obtained from:

Foundations' Fund for Research in Psychiatry
100 York Street
New Haven, Connecticut 06511

ANNUAL INDEX

Following is the comprehensive index for volume 135 of the *Journal*, covering all material from January 1978 through December 1978. The complete citation for each article in the author index is listed under the name of the first author. Joint authors are listed alphabetically with a cross-reference to the first author; cross-references containing more than one first author name separated by semicolons indicate multiple articles by the joint author. Book reviews appear in the author index under the name of the reviewer and in the subject index under the heading Books Reviewed; the books are arranged alphabetically by the surname of the book's first author.

Effective this year, listings in the subject index are according to key words rather than subject categories. In addition, all entries are in abbreviated style. Each entry in the subject index is identified by the surname of the first author only; semicolons indicate multiple works (e.g., letters to the editor). Two-letter abbreviations for the months are used, and entries other than regular articles, brief communications, and clinical and research reports are given the following designations: book review (bk rev), letter to the editor (ltr to ed), editorial (edt), in memoriam (in mem), and official actions (off acts).

SUBJECT INDEX

A

Abortion, Therapeutic
psychoses following. Spaulding, Mr, 364–365
Abuse see Child Abuse; Fraud; Spouse Abuse
Academic Achievement
high, in psychotic students. DeFries, Fe, 217–219
Acetaminophen
overdose. Silverman, Ja, 114–115
Acetylation Phenotype
platelet monoamine oxidase inhibition, effectiveness of phenelzine in depression, and. Davidson, Ap, 467–469
Activation-Synthesis Hypothesis see Dream Theory
Acute Mental Illness
temporal disorganization, depersonalization, and persecutory ideation in. Freeman, Ja, 123–124
Adaptation see Sociobiology
Addiction see also Drug Abuse
to placebo (ltr to ed). Vinar, Au, 1000
***S*-Adenosylmethionine-dependent *N*-Methyltransferase**
activity in autopsied brain parts of chronic schizophrenics and controls. Erdelyi, Je, 725–728
Administrators
becoming an administrator, vicissitudes of middle management in mental health organizations. Dressler, Mr, 357–360
psychopathology of team concept (ltr to ed). Favis, reply of Dressler, Se, 1117–1118
Adolescents
adolescent suicide, epidemiological study of recent trends. Holinger, Je, 754–756
Gilles de la Tourette's syndrome, tardive dyskinesia, and psychosis in an adolescent. Caine, Fe, 241–243
grocery store high. Block, Ja, 126–127
tardive dyskinesia in adolescent. McLean, Au, 969–971
34, with cerebral palsy, coping styles of. Minde, No, 1344–1349
treated with high-potency antipsychotics, extrapyramidal reactions in. Chiles, Fe, 239–240
Adoptees
evidence for genetic inheritance of primary affective disorder in. Cadoret, Ap, 463–466
Adrenergic Receptors see Neuroreceptors
Adult Development
mid-adult development and psychopathology. Stein, Je, 676–681
natural history of male psychological health, VI. correlates of successful marriage and fatherhood. Vaillant, Je, 653–659
Affective Disorders see also Depression
anniversary reaction or? (ltrs to ed). Merrin; Rapp, reply of Cavenar, Ap, 501–502
application of EEG sleep for differential diagnosis of. Kupfer, Ja, 69–74
cerebrospinal fluid norepinephrine in affective illness. Post, Au, 907–912
cyclothymic disorder as bipolar illness (ltr to ed). Flemenbaum, reply of Akiskal, Au, 996–997
heritable disorder of lithium transport in erythrocytes of subpopulation of manic-depressive patients. Ostrow, Se, 1070–1078
Klinefelter's syndrome and bipolar affective illness, case report. Caroff, Je, 748–749
manic-depression or acute schizophrenia? (ltr to ed). Farber, reply of White, Mr, 388
manic-depressive illness associated with Klinefelter's syndrome and essential tremors (ltr to ed). Lesage, Je, 757–758
paranoid episodes in manic-depressive psychoses. Fry, Au, 974–976
plasma 3-methoxy-4-hydroxyphenylglycol in manic psychosis. Halaris, Ap, 493–494
primary, in adoptees, evidence for genetic inheritance of. Cadoret, Ap, 463–466
primary, social adjustment in. Dunner, No, 1412–1413
prophylactic effect of lithium and imipramine in unipolar and bipolar II patients, preliminary report. Quitkin, My, 570–572
psychiatric illness in relatives of patients with Parkinson's disease, expanded survery. Winokur, Jy, 854–855
rating scale for emotional blunting. Abrams, Fe, 226–229
retrospective diagnosis of hypomania following successful treatment of episodic violence with lithium, case report. Cutler, Je, 753–754
sexual function and affect in parkinsonian men treated with L-dopa. Brown, De, 1552–1555
treatment of imipramine-resistant depression and lithium-refractory mania through drug interactions. Meyers, No, 1420–1421
trimipramine and relapses of symptomatic drinking (ltr to ed). Kubacki, reply of Akiskal, Oc, 1245
urinary 3-methoxy-4-hydroxyphenylglycol and psychiatric diagnosis. Taube, Ja, 78–82
Aftercare
how many patients are "nondischargeable"? (ltr to ed). Lewis, My, 620
patients' views of placement facilities, participant-observer study. Christenfeld, Mr, 329–332
Aggression see also Violence
paradoxical response to tricyclic antidepressants. Rampling, Ja, 117–118
splitting and identification with aggressor in assaultive borderline patients. MacVicar, Fe, 229–231
usefulness of lithium for aggressiveness (ltr to ed). Tupin, Se, 1118
Aging see Geriatric Psychiatry
Agonists, Opiate see Opiate Agonists
Agranulocytosis
routine WBCs and, in children. Piggott, Au, 977–978
Akathisia
dystonia and, acute, neuroleptic-induced, intravenous diazepam in treatment of. Gagrat, Oc, 1232–1233
Alcohol
consumption, effect of, on state anxiety changes in male and female nonalcoholics. Logue, Se, 1079–1081
Alcoholism
cause and effect in "alcoholic tremor" (ltr to ed). Massey, De, 1572
conventional wisdom as approach to (ltr
Pattison, Au, 994–995
differential diagnosis in recognizing (ltr
hu, Jy, 871
procedures for taste aversion therapy
ed). Baker, No, 1439
taste aversions to alcoholic beverages
by motion sickness. Mellor, Ja, 125–
trimipramine and relapses of symptomat
ing (ltr to ed). Kubacki, reply of Akiska
1245
Amenorrhea
anniversary reaction and, in woman present
with chest pain. Miller, Ja, 120–
American Board of Psychiatry and Neurology
American Board of Psychiatry and Neurology (off acts). Mr, 408–412
American Board of Psychiatry and Neurology (off acts). Je, 780
American Board of Psychiatry and Neurology (off acts). No, 1457–1464
feedback for part I of Boards (ltr to ed). Middlekauff, reply of Rudy, Jy, 873
1977 annual report of American Board of Psychiatry and Neurology, Inc. (off act Rudy, Oc, 1302–1304
vote for patient interviews in Board exams (ltr to ed). Gellar, Mr, 382
American Journal of Psychiatry
changes on masthead of AJP. Brace ard, Je, 720–721
on editing Journal, ave atque vale. Braceland, Oc, 1148–1155
editorial double standards? (ltr to ed Taylor, De, 1572
Editor's valedictory (edtl). Braceland, Je, 717–719
fond letter to Editor. Nemiah, Jy Supp, 1
Francis J. Braceland, Editor, music will play on. Myers, Jy, 789–791
Francis J. Braceland, man. Rome, Jy, 784–788
new year greetings and card of thanks (edtl). Braceland, Ja, 87–91
thirteen years before masthead, editorial pictures. Nemiah, Jy, 783
American Psychiatric Association
Assembly of District Branches (off acts), Fe, 291–292
Commission on Certification in Administrative Psychiatry (off acts). Au, 1028

ECT versus (ltr to ed). Abrams, reply of Cole, Ap, 500-501
generic versus brand name psychotropics (ltr to ed). Ayd, No, 1428
monitoring plasma concentrations of (ltr to ed). Hollister, My, 618
plasma and erythrocyte levels of, in depressed patients. Linnoila, My, 557-561
plasma levels and clinical findings in overdose. Bailey, No, 1325-1328
platelet MAO inhibition following tricyclic antidepressant therapy. Davidson, My, 603-605
prediction of imipramine antidepressant response by one-day *d*-amphetamine trial. Van Kammen, Oc, 1179-1184
sleep deprivation in depression (ltrs to ed). Wehr; Linn, reply of Christodoulou, Au, 1000-1001
speech blockage, therapeutic side effect? (ltr to ed). Schnee, reply of Schatzberg, Oc, 1246
speech blockage, tricyclic side effect. Schatzberg, My, 600-601
speech blockage in young patients taking tricyclics (ltr to ed). Sholomskas, reply of Schatzberg, De, 1572-1573
successful treatment of severe anxiety attacks with, potential mechanism of action. Jobson, Jy, 863-864
tardive dyskinesia and pharmacotherapy (ltr to ed). Rosenbaum, Ap, 506
treating tricyclic overdose with physostigmine (ltr to ed). Ordiway, Se, 1114
tricyclic overdose in patient given combined tricylic-MAOI treatment. White, No, 1411-1412
tricyclics, bioequivalence, and clinical response. Ostroff, De, 1560-1561
two, anticholinergic activity of. Blackwell, Je, 722-724
weight loss and concomitant change in plasma tricyclic levels. Jobson, Fe, 237-238
Antiparkinsonian Agents
interactive effects of trihexyphenidyl and coffee (ltr to ed). Weinstock, reply of MacVicar, My, 624-625
levodopa-induced psychosis, kindling pheonomenon. Moskovitz, Je, 669-675
mental disturbances during bromocriptine and lergotrile treatment of Parkinson's disease. Serby, Oc, 1227-1229
nonconfusional paranoid psychosis secondary to anticholinergics? (ltr to ed). Moore, reply of Klawans, De, 1574
Antipsychotic Agents
addition of reserpine to antipsychotic medication in refractory chronic schizophrenic outpatients. Bacher, Ap, 488-489
clozapine plasma levels and convulsions. Simpson, Ja, 99-100
controlled study of penfluridol in treatment of chronic schizophrenia. Lapierre, Au, 956-959
differential diagnosis in recognizing alcoholism (ltr to ed). Sidhu, Jy, 871
drug history and tardive dyskinesia. Smith, No, 1402-1403
eye blink and schizophrenia, psychosis or tardive dyskinesia? Stevens, Fe, 223-226
on guidelines for maximum dosages (ltr to ed). Shader, reply of Crane, Ap, 499
high-potency, extrapyramidal re[illegible] cents treated with. Chiles, Fe, [illegible]
"HMC" treatment recalled (ltr [illegible] ermeyer, Jy, 868-869
impact of neuroleptic chemother[illegible] phrenic psychoses. Deniker, [illegible]

research priorities in Asian-[illegible] health delivery. Yamamoto, A[illegible]
service delivery issues in Asian [illegible] communities. Lin, Ap, 454-45[illegible]

Asphyxia
with haloperidol treatment, laryngeal-pharyngeal dystonia as possible cause of. Flaherty, No, 1414–1415
Assessment, Psychiatric
evaluation models and theoretical bias (ltr to ed). Roberts, reply of Nason, Au, 511
evaluation of patients referred for psychiatric treatment (ltr to ed). Solomon, reply of Bittker, Au, 995–996
failure to detect low IQ in. Gift, Mr, 345–349
Asterixis
post-ECT, associated with primary hyperparathyroidism. Dysken, Oc, 1237–1238
Asthma
more on lithium and (ltr to ed). Winig, Au, 988
possible positive "side effects" of lithium (ltr to ed). Putnam, Mr, 388
Atropine Delirium
anticholinergic delirium in case of Munchausen syndrome. Hollender, No, 1407–1409
Autistic Children
effect of high doses of vitamin B_6 on, double-blind crossover study. Rimland, Ap, 472–475
megavitamin therapy for (ltr to ed). Moss, reply of Callaway, No, 1425–1426
minor physical anomalies in young psychotic children. Campbell, My, 573–575
Autonomic Nervous System
cardiovascular excitability and emotional stress (ltr to ed). Hoehn-Saric, reply of Dimsdale, Se, 1116

B

Baclofen
in treatment of tardive dyskinesia. Nair, De, 1562–1563
Bank Robbery
psychological observations of. Johnston, No, 1377–1379
Barbiturates
more on tardive dyskinesia and (ltr to ed). Sovner, Mr, 382
Battered Children see Child Abuse
Battered Wives see Spouse Abuse
Behavior Therapy
catharsis during prolonged exposure for snake phobia, agent of change? Hafner, Fe, 247–248
novel symptom emergence after, in case of hypodermic injection phobia. Hsü, Fe, 238–239
severe depersonalization treated by. Sookman, De, 1543–1545
taste aversions to alcoholic beverages conditioned by motion sickness. Mellor, Ja, 125–126
Benzodiazepines see also Diazepam
oral-buccal dyskinesia symptoms associated with low-dose benzodiazepine treatment. Kaplan, De, 1558–1559
Bereavement see Grief
Betel Nut see Arecaidine
Bioequivalence
generic versus brand name psychotropics (ltr to ed). Ayd, No, 1428
tricyclics, clinical response, and. Ostroff, De, 1560–1561
Biological Model
anthropological cross-fertilization (ltr to ed). Jonas, reply of Favazza, Se, 1113–1114
illusion of simplicity, medical model revisited. Weiner, Jy Supp, 27–33
Bite
phantom, syndrome. Marbach, Ap, 476–479
Blacks
training psychiatrists for working with, in basic residency programs. Bradshaw, De, 1520–1524
when psychotherapist is black. Cavenar, Se, 1084–1087
Blood Pressure see Hypertension
Blood Types
ABO, hysteria and. Rinieris, Se, 1106–1107

kovitz, Jo, 669-675
nonconfusional paranoid psychosis secondary to anticholinergics? (ltr to ed). Moore, reply of Klawans, De, 1574
paradoxical reaction to, in schizophrenic patients. Alpert, No, 1329-1332
sexual function and affect in parkinsonian men treated with. Brown, De, 1552-1555
suppression of prolactin by dopamine agonists in schizophrenics and controls. Rotrosen, Au, 949-951

Dopamine Agonists
mental disturbances during bromocriptine and lergotrile treatment of Parkinson's disease. Serby, Oc, 1227-1229
serum prolactin increased by exogenous and endogenous opiates, evidence for antidopamine and antipsychotic effects. Gold, No, 1415-1416
suppression of prolactin by, in schizophrenics and controls. Rotrosen, Au, 949-951
on use of, in tardive dyskinesia (ltr to ed). Barnes, reply of Smith, Ja, 132-133

Dopamine Receptors
in pituitary and striatum, effect of haloperidol and apomorphine treatment on. Friend, Jy, 839-841

Dosage
individual, of nortriptyline, prediction of, Cooper, Mr, 333-335
maximum, on guidelines for (ltr to ed). Shader, reply of Crane, Ap, 499-500

Doubles see Subjective Doubles

Doxepin HCl
weight loss and concomitant change in plasma tricyclic levels. Jobson, Fe, 237-238

Dreams
levodopa-induced psychosis, kindling phenomenon. Moskovitz, Je, 669-675
recurrent, as precipitant. Cavenar, Mr, 378-379

Dream Theory
activation-synthesis hypothesis of dreams, theoretical note. LaBruzza, De, 1536-1538
alternative view of neurobiology of dreaming. Vogel, De, 1531-1535
neurobiology and dreams, further queries (ltrs to ed). Grubbs; Charney; Walls, reply of McCarley, No, 1430-1434
neurology and, queries (ltrs to ed). Nininger; Wexler; Naiman; Ginsburg; LaBruzza; Lomas; Hall, reply of McCarley, My, 613-618

Dropouts see Patient Dropouts

Drug Abuse
acetaminophen overdose. Silverman, Ja, 114-115
animal-human correlates of narcotic dependence, brief review. Stimmel, Jy, 821-825
cocaine hallucinations. Siegel, Mr, 309
drug use by polysurgical patient. DeVaul, Je, 682-685
grocery store high. Block, Ja, 126-127
interactive effects of trihexyphenidyl and coffee (ltr to ed). Weinstock, reply of MacVicar, My, 624-625
marijuana use in schizophrenia, clear hazard. Treffert, Oc, 1213-1215
methylphenidate-induced choreoathetosis. Extein, Fe, 252-253
nutmeg abuse (ltr to ed). Dinakar, De, 1571
popping and snorting volatile nitrites, current fad for getting high. Sigell, Oc, 1216-1218
prescription drug-induced organic brain syndrome. Maruta, Mr, 376-377
prescription drug-induced organic brain syndrome (ltr to ed). Shen, Se, 1116-1117
psychoanalytic observations on marijuana use. Wallace, Au, 990-991
"spice cabinet" intoxication. Faguet, Jy, 860-861
treating phencyclidine intoxication (ltr to ed). Schaffer, Mr, 388

Drug Interactions
treatment of imipramine-resistant depression and lithium-refractory mania through. Meyers, No, 1420-1421

Drug Side Effects see also Extrapyramidal Symptoms; Tardive Dyskinesia
aggression, paradoxical response to tricyclic antidepressants. Rampling, Ja, 117-118
cardiac effects of therapeutic plasma concentrations of imipramine. Kantor, My, 534-538
chlorpromazine-induced PIE syndrome. Shear, Ap, 492-493
digitalis delirium, report of two cases. Shear, Ja, 109-110
disulfiram and CS_2 toxicity (ltr to ed). Faiman, reply of Rainey, My, 623-624
factors influencing phenothiazine-induced ECG changes. Nasrallah, Ja, 118
filicide during psychotropic-induced somnambulism, case report. Luchins, No, 1404-1405
hyperthermia associated with chlorpromazine and full-sheet restraint. Greenland, Oc, 1234-1235
improved psychological status of children under DDAVP therapy for central diabetes insipidus. Waggoner, Mr, 361-362
inhibition of ejaculation by amitriptyline. Nininger, Je, 750-751
levodopa-induced psychosis, kindling phenomenon. Moskovitz, Je, 669-675
neurobiological vulnerability to low-dose amphetamine psychosis. Gold, De, 1546-1548
marijuana use in schizophrenia, clear hazard. Treffert, Oc, 1213-1215
mental disturbances during bromocriptine and lergotrile treatment of Parkinson's disease. Serby, Oc, 1227-1229
more on lithium and asthma (ltr to ed). Winig, Au, 998
neuroleptic-induced hypersensitivity psychosis. Chouinard, No, 1409-1410
nonconfusional paranoid psychosis secondary to anticholinergics? (ltr to ed). Moore, reply of Klawans, De, 1574
organic impairment in polydrug users, risk factors. Grant, Fe, 178-184
phenelzine and delusions of parasitosis, case report. Liebowitz, De, 1565-1566
phenelzine-induced psychosis. Sheehy, No. 1422-1423
popping and snorting volatile nitrites, current fad for getting high. Sigell, Oc, 1216-1218
positive side effects of lithium? (ltr to ed). Christodoulou, Oc, 1249
possible positive "side effects" of lithium (ltr to ed). Putnam, Mr, 388
postprandial ECG (ltr to ed). Schiff, reply of Nasrallah, Se, 1115-1116
prescription drug-induced organic brain syndrome. Maruta, Mr, 376-377
prescription drug-induced organic brain syndrome (ltr to ed). Shen, Se, 1116-1117
psychotropic drugs, summer heat and humidity, and hyperpyrexia, danger restated. Mann, Se, 1097-1100
routine WBCs and agranulocytosis in children. Piggott, Au, 977-978
sexual function and affect in parkinsonian men treated with L-dopa. Brown, De, 1552-1555
side effects in neonate from psychotropic agents excreted through breast-feeding. Ananth, Jy, 801-805
speech blockage, therapeutic side effect? (ltr to ed). Schnee, reply of Schatzberg, Oc, 1246
speech blockage, tricyclic side effect. Schatzberg, My, 600-601
speech blockage in young patients taking tricyclics (ltr to ed). Sholomskas, reply of Schatzberg, De, 1572-1573
treating tricyclic overdose with physostigmine (ltr to ed). Ordiway, Se, 1114
treatment for dry mouth in psychiatric patients. Fann, Fe, 251-252

Drugs, Psychotropic see Psychotropic Drugs

Dry Mouth
treatment for, in psychiatric patients. Fann, Fe, 251-252

Dualism, Psychic
mind-body dichotomy reified, illustrative case. Schoenberg, Oc, 1224-1226

Dystonia
akathisia and, acute, neuroleptic-induced, intravenous diazepam in treatment of. Gagrat, Oc, 1232-1233
disorder often misdiagnosed as conversion reaction. Lesser, Mr, 349-352
laryngeal-pharyngeal, as possible cause of asphyxia with haloperidol treatment. Flaherty, No, 1414-1415

E

ECG
phenothiazine-induced changes, factors influencing. Nasrallah, Ja, 118-119
postprandial (ltr to ed). Schiff, reply of Nasrallah, Se, 1115-1116

Eclecticism
empiricism and, in psychiatry (ltr to ed). Kendler, reply of Yager, Ja, 131-132

ECT
author stands corrected (ltr to ed). Rice, reply of Salzman, Mr, 386
bilateral and unilateral, effects on verbal and nonverbal memory. Squire, No, 1316-1320
cerebral dominance and (ltr to ed). Eastwood, Ap, 510-511
for depressed patients with lupus erythematosus. Allen, Mr, 367-368
-induced blood pressure elevations, sodium nitroprusside treatment of. Ciraulo, Se, 1105-1106
in metropolitan New York hospitals, survey of practice, 1975-1976. Asnis, Ap, 479-482
post-ECT asterixis associated with primary hyperparathyroidism. Dysken, Oc, 1237-1238
in pregnancy (ltr to ed). Remick, Je, 761-762
prolactin changes during. O'Dea, My, 609-611
research, early (ltr to ed). Kalinowsky, Ja, 134
single-blind study of, in patients with tardive dyskinesia. Asnis, Oc, 1235-1237
therapy, effects of, on tardive dyskinesia. Price, Au, 991-993
tricyclic antidepressants and, intrapatient responses to. Coryell, Se, 1108-1110
tricyclics versus (ltr to ed). Abrams, reply of Cole, Ap, 500-501

Editorials
changes on masthead of AJP. Braceland, Je, 720-721
children of idle brain? Nemiah, De, 1530
Editor's valedictory. Braceland, Je, 717-719
lithium, developments in basic and clinical research. Lipton, Se, 1059-1061
new year greetings and card of thanks. Braceland, Ja, 87

Education Groups
educational approach to short-term hospitalization (ltr to ed). Blue, Oc, 1246-1247

Education, Medical
bent twig, psychiatry and. Klein, Mr, 320-324
family practitioner as psychiatrist. Feldman, Je, 728-731
internship year, negative view. Halleck, Oc, 1202-1205; comment by Romano, 1206-1209
medical school admission screening by psychiatrists (ltr to ed). Hansen, No, 1434
medical-student spouse syndrome, grief reactions to clinical years. Robinson, Au, 972-974
"nourishing concern" for patients as people in (ltr to ed). Benor, reply of Fink, Mr, 382-383
physician's knowledge of psychotropic drugs, preliminary results. Gottlieb, Ja, 29-32
primary care/mental health training and service model. Adams, Ja, 121-123
psychiatric consultation in HMO, model for education in primary care. Rittelmeyer, Se, 1089-1092

psychiatric training for primary care obstetrician-gynecologist resident. Boekelheide, Se, 1087-1088
what medical students should know about psychiatry, results of survey of rural general practitioners. Callen, Fe, 243-244

Education, Psychiatric see also Residency Records; Residents, Psychiatric
adult psychiatrist in medical environment. Moore, Ap, 413-419
consultation-liaison versus other psychiatry clerkships, comparison of learning outcomes and student reactions. Weddington, De, 1509-1512
education and training of Asian foreign medical graduates in United States. Chen, Ap, 451-453
geriatric psychiatry training for general psychiatric resident. Finkel, Ja, 101-103
group therapy training in psychiatric residency programs, national survey. Pinney, De, 1505-1508
internship year, negative view. Halleck, Oc, 1202-1205; comment by Romano, 1206-1209
national survey of resident assessment methods. Procci, Jy, 845-847
new mental health profession (ltr to ed). Zulver, Je, 758
other views on women in psychiatric residency (ltrs to ed). Kessler; Gregory, reply of Barton, Se, 1111-1112
physician's knowledge of psychotropic drugs, preliminary results. Gottlieb, Ja, 29-32
proper knowledge of psychotropic medications (ltr to ed). Pakes, Jy, 874
psychiatric training for primary care obstetrician-gynecologist resident. Boekelheide, Se, 1087-1088
psychiatry residents in milieu participatory democracy, resident's view. Gersten, No, 1392-1395
role of infant observation in child psychiatry training. Greenman, Oc, 1174-1178
supervision and professional development of psychiatric resident. Drucker, De, 1518-1519
training of Asian and Asian-American psychiatrists and. Wong, De, 1525-1529
training psychiatrists for working with blacks in basic residency programs. Bradshaw, De, 1520-1524
transition to practice seminar. Borus, De, 1513-1516
videotape recording of dynamic psychotherapy, supervisory tool or hindrance? Friedmann, No, 1388-1391

EEG
sleep, application of, for differential diagnosis of affective disorders. Kupfer, Ja, 69-74

Ejaculation
inhibition of, by amitriptyline. Nininger, Je, 750-751

Emergency Psychiatry
are clinicians afraid to ask about violence (ltr to ed). Lion, Je, 757
assaultive patient and. Skodol, Fe, 202-205
assessment of depression, model for quality review of. Kass, Fe, 213-216
decision to hospitalize. Feigelson, Mr, 354-357
prediction research and emergency commitment of dangerous mentally ill patients, reconsideration. Monahan, Fe, 198-201
psychiatrists' familiarity with legal statutes governing emergency involuntary hospitalization. Affleck, Fe, 205-209
referrals from psychiatric emergency room, relationship of compliance to demographic and interview variables. Jellinek, Fe, 209-213

Emotional Blunting
rating scale for. Abrams, Fe, 226-229

Emotional Stress
cardiovascular excitability and (ltr to ed). Hoehn-Saric, reply of Dimsdale, Se, 1116

in tardive dyskinesia (ltr to ed). Simpson, Jy, 865
Gastrointestinal Complications
tardive dyskinesia as life-threatening illness. Casey, Ap, 486-488
General Practice see Primary Care
Generic vs Brand-Name Drugs see Bioequivalence
Genetic Counseling
for psychiatric patients and their families. Tsuang, De, 1465-1475
Genetic Disease
psychosocial aspects of Tay-Sachs screening clinic. Schneiderman, Se, 1101-1102
Genetic Factors in Mental Illness
evidence for genetic inheritance of primary affective disorder in adoptees. Cadoret, Ap, 463-466
manic-depressive illness associated with Klinefelter's syndrome and essential tremors (ltr to ed). Lesage, Je, 757-758
Geriatric Psychiatry
Capgras syndrome in old age (ltrs to ed). Granacher; Schlesinger, reply of Weiner, Je, 758-759
chronic brain disease, overview. Wells, Je, 1-12
myth of pseudodementia, depression and aging brain. Shraberg, My, 601-603
psychiatric house call. Gurian, My, 592-593
thoughts on aging. Butler, Jy Supp, 14-16
training, for general psychiatric resident. Finkel, Ja, 101-103
Gilles de la Tourette's Syndrome
comparison of pimozide and haloperidol in treatment of. Ross, My, 585-587
tardive dyskinesia, psychosis, and, in adolescent. Caine, Fe, 241-243
Gluten
in schizophrenia, another look at. Rice, No, 1417-1418
Grief see also Anniversary Reaction
differentiating mourning, bereavement, and (ltr to ed). Graves, reply of Greenblatt, Jy, 874-875
differentiating narcolepsy (ltr to ed). Rockwell, reply of Shapiro, Mr, 387
grieving spouse. Greenblatt, Ja, 43-47
reactions to clinical years, medical-student spouse syndrome. Robinson, Au, 972-974
Group Therapy
group psychotherapy dropout phenomenon revisited. Lothstein, De, 1492-1495
"relief effect," sociobiological model for neurotic distress and large-group therapy. Galanter, My, 588-591
training in psychiatric residency programs, national survey. Pinney, De, 1505-1508

H

Hallucinations
cocaine. Siegel, Mr, 309
levodopa-induced psychosis, kindling phenomenon. Moskovitz, Je, 669-675
nonconfusional paranoid psychosis secondary to anticholinergics? (ltr to ed). Moore, reply of Klawans, De, 1574
Haloperidol
apomorphine and, treatment, effect of, on dopamine receptors in pituitary and striatum. Friend, Jy, 839-841
comparison of pimozide and, in treatment of Gilles de la Tourette's syndrome. Ross, My, 585-587
safe use of, in patient with cardiac dysrhythmia (ltr to ed). Cameron, Oc, 1244
thyroid storm and. Hoffman, Ap, 484-486; correction, Je, 762
treatment, for delirium, question on (ltr to ed). Cutler, reply of Moore, Jy, 871-872
treatment, laryngeal-pharyngeal dystonia as possible cause of asphyxia with. Flaherty, No, 1414-1415
Handedness
cerebral dominance and ECT (ltr to ed). Eastwood, Ap, 510-511
Health Maintenance Organizations
evolution of psychiatric services in. Bittker, Mr, 339-342
external provision of health maintenance organization mental health services. Muller, Je, 735-738
mental health services in (ltr to ed). Bennett, reply of Muller, Oc, 1249-1250
psychiatric consultation in, model for education in primary care. Rittelmeyer, Se, 1089-1092
Hearst Trial
confidentiality of residency records, two responses (ltrs to ed). Sheehy; Kessenick, reply of Terr, Ap, 502-506
Heat
summer, humidity and, psychotropic drugs, hyperpyrexia, and, danger restated. Mann, Se, 1097-1100
Hematologic Changes see also Leukopenia
in anorexia nervosa. Rieger, Au, 984-985
Hemispheric Specialization see Cerebral Lateralization
Hemodialysis
dangers of indirect data (ltr to ed). Van den Berg, reply of Snyder, De, 1569-1570
effect of, on schizophrenia, survey of patients with renal failure. Port, Je, 743-744
patients, children of and selection of setting. Evans, Mr, 343-345
selection criteria for dialysis and renal transplant. Rabinowitz, Jy, 861-863
Heroin see Opiate Dependence
History
another historical note (ltr to ed). Halpern, reply of Monahan, My, 618-619
psychiatrist and. Musto, Jy Supp, 22-26
reflections on military psychiatry. Arthur, Jy Supp, 2-7
trends in American mental health. Redlich, Ja, 22-28; discussion by Brody, 28
HMC
treatment recalled (ltr to ed). Westermeyer, Jy, 868-869
Home Movies
of prepsychotic and normal infants, blind ratings of mother-infant interaction in. Massie, No, 1371-1374
Homosexuality
father-son incest, underreported psychiatric problem? Dixon, Jy, 835-838
more on neglected problem (ltr to ed). Esman, No, 1438
pseudohomosexuality in male patients with hysterical psychosis, preliminary report. Miller, Ja, 112-113
sexual identity of 37 children raised by homosexual or transsexual parents. Green, Je, 692-697
testosterone levels and women's sexual preference (ltr to ed). Gartrell, De, 1574
Hormones
clinical and neuroendocrine correlates of elevated platelet MAO activity (ltr to ed). De la Fuente, Au, 994
testosterone levels and women's sexual preference (ltr to ed). Gartrell, De, 1574
Hospitalization see also Seclusion
decision to hospitalize. Feigelson, Mr, 354-357
highlighting need for alternatives to (ltr to ed). Solomon, reply of Slaughter, Mr, 386-387
how many patients are "nondischargeable"? (ltr to ed). Lewis, My, 620
patients' views of placement facilities, participant-observer study. Christenfeld, Mr, 329-332
psychiatric, of children, developmental issues in. Berlin, Se, 1044-1048
transfer of chronically ill? (ltr to ed). Har-Esh, Ap, 499
Hospitalization, Brief
brief versus standard hospitalization, differential costs. Endicott, Je, 707-712
educational approach to (ltr to ed). Blue, Oc, 1246-1247
Hospitalization, Involuntary see Commitment
Hospitalization, Partial
another reason for underutilization of? (ltr to ed). Tishler, reply of Fink, No, 1428-1429
brief versus standard hospitalization, differential costs. Endicott, Je, 707-712
day hospital treatment of borderline patients, clinical perspective. Pildis, My, 594-596
paradoxical underutilization of. Fink, Je, 713-716
Hospitalization, Pretrial see Commitment
Hospitals
families and, collusion or cooperation? Harbin, De, 1496-1499
marketplace model of consultation psychiatry in general hospital. Guggenheim, No, 1380-1383
Hospitals, Children's
children's psychiatric hospital unit in community, I. concept and development. Blinder, Jy, 848-851
developmental issues in psychiatric hospitalization of children. Berlin, Se, 1044-1048
Hospitals, Private Psychiatric
"excellence is their watchword." Gibson, Jy Supp, 17-21
Hospitals, Use of ECT in
ECT in metropolitan New York hospitals, survey of practice, 1975-1976. Asnis, Ap, 479-482
House Calls
psychiatric. Gurian, My, 592-593

Humanistic Approach
"nourishing concern" for patients as people in medical education (ltr to ed). Benor, reply of Fink, Mr, 382-383
Huntington's Disease
sodium valproate in. Symington, Mr, 352-354
Hyperkinesis
crossover study of artificial food colorings in hyperkinetic child. Mattes, Au, 987-988
diet and, replication study. Levy, De, 1559-1560
hyperkinetic/aggressive boys in treatment, predictors of clinical response to methylphenidate. Loney, De, 1487-1491
Hyperparathyroidism
primary, post-ECT asterixis associated with. Dysken, Oc, 1237-1238
Hyperpyrexia see Hyperthermia
Hypersensitivity Psychosis
neuroleptic-induced. Chouinard, No, 1409-1410
Hypertension
severe, treated successfully by marital psychotherapy. Summers, Au, 989-990
sodium nitroprusside treatment of ECT-induced blood pressure elevations. Ciraulo, Se, 1105-1106
Hyperthermia
associated with chlorpromazine and full-sheet restraint. Greenland, Oc, 1234-1235
psychotropic drugs, summer heat and humidity, and hyperpyrexia, danger restated. Mann, Se, 1097-1100
Hypnosis
related clinical behavior and. Frankel, Je, 664-668
Hypnotics see Sodium Amylobarbitone
Hypochondriasis
phantom bite syndrome. Marbach, Ap, 476-479
two cases of delusions of worm infestation. Munro, Fe, 234-235
Hysteria
ABO blood types and. Rinieris, Se, 1106-1107
Briquet's syndrome and (ltr to ed). Slavney, reply of Liskow, Je, 759-760
neurogenic and hysterial seizures in children and adolescents, differential diagnostic and therapeutic considerations. Williams, Ja, 82-86
pseudohomosexuality in male patients with hysterical psychosis, preliminary report. Miller, Ja, 112-113
split asunder. Hyler, De, 1500-1504

I

Ictal Psychosis
false positives in differential diagnosis of confusion with amytal (ltr to ed). Shevitz, reply of Ward, Jy, 869-870
Imipramine see also Psychotropic Drugs; Tricyclic Antidepressants
antidepressant response, prediction of, by one-day *d*-amphetamine trial. Van Kammen, Oc, 1179-1184
cardiac effects of therapeutic plasma concentrations of. Kantor, My, 534-538
hydrochloride, enuresis treatment with, 10-year follow-up study with. Bindelglas, De, 1549-1552
oral dyskinesia or myoclonus? (ltr to ed). Moskovitz, reply of Ramsey, My, 622-623
prophylactic effect of lithium and, in unipolar and bipolar II patients, preliminary report. Quitkin, My, 570-572
-resistant depression and lithium-refractory mania, treatment of, through drug interactions. Meyers, No, 1420-1421
response in deluded depressive patients. Quitkin, Jy, 806-811
Impotence
diabetic, nocturnal tumescence and diagnosis in. Karacan, Fe, 191-197
Incest
father-son, underreported psychiatric problem? Dixon, Jy, 835-838
more on neglected problem (ltr to ed). Esman, No, 1438
Indirect Data
dangers of (ltr to ed). Van den Berg, reply of Snyder, De, 1569-1570
Infants
prepsychotic and normal, home movies of, blind ratings of mother-infant interaction in. Massie, No, 1371-1374
role of infant observation in child psychiatry training. Greenman, Oc, 1174-1178
side effects in neonate from psychotropic agents excreted through breast-feeding. Ananth, Jy, 801-805
some determinants of maternal attachment. Peterson, Oc, 1168-1173
sudden infant death syndrome, impact on families and direction for change. Weinstein, Jy, 831-834; correction, Se, 1118
Inner-Outer Confusion
or disorder of self-experience? (ltr to ed). Kerner, reply of Melges, Mr, 383-384
Insurance
CHAMPUS coverage (ltr to ed). Solomon, Ap, 509-510
CHAMPUS payment limitations (ltr to ed). Hauser, reply of Solomon, Oc, 1247
clinics, private practice, and national health insurance (ltr to ed). Upton, reply of Langsley, De, 1574-1575
fraud and abuse in psychiatric practice. Towery, Ja, 92-94
psychiatry and fiscal third party. Chodoff, Oc, 1141-1147
third-party payers, to pay or not to pay. Sharfstein, Oc, 1185-1188
utilization and cost of mental illness coverage in Federal Employees Health Benefits Program, 1973. Hustead, Mr, 315-319
Intermetamorphosis Syndrome
organic contributors to. Malliaras, Au, 985-987
International Pilot Study of Schizophrenia
signs and symptoms as predictors of outcome, report from. Carpenter, Au, 940-945
Internship see Education, Medical
Intracranial Disease see Brain
IQ
low, failure to detect, in psychiatric assessment. Gift, Mr, 345-349

clinical relevance of anthropological and cross-cultural research, concepts and strategies. Kleinman, Ap, 427-431
clinics, private practice, and national health insurance (ltr to ed). Upton, reply of Langsley, De, 1574-1575
comparing clinic and private practice of psychiatry. Langsley, Je, 702-706
ethics in, origins, functions, models, and enforcement. Moore, Fe, 157-163
evolution of psychiatric services in health maintenance organization. Bittker, Mr, 339-342
fraud and abuse in psychiatric practice. Towery, Ja, 92-94
physician's knowledge of psychotropic drugs, preliminary results. Gottlieb, Ja, 29-32
psychiatric house call. Gurian, My, 592-593
psychiatrists' familiarity with legal statutes governing emergency involuntary hospitalization. Affleck, Fe, 205-209
psychiatry and fiscal third party. Chodoff, Oc, 1141-1147
Psychoanalysis
obesity and. Rand, My, 547-551; correction, Se, 1118
psychoanalytic observations on marijuana use. Wallace, Au, 990-991
Psychoanalytic Theory
activation-synthesis hypothesis of dreams, theoretical note. LaBruzza, De, 1536-1538
alternative view of neurobiology of dreaming. Vogel, De, 1531-1535
dream theory and neurology, queries (ltrs to ed). Nininger; Wexler; Naiman; Ginsburg; LaBruzza; Lomas; Hall, reply of McCarley. My, 613-618
neurobiology and dreams, further queries (ltrs to ed). Grubbs; Charney; Walls, reply of McCarley, No, 1430-1434
Psychobiological Research see Research
Psychopathology
mid-adult development and. Stein, Je, 676-681
Psychosis
acute, precipitated by withdrawal of anticonvulsant medication. Demers-Desrosiers, Au, 981-982
low-dose amphetamine, neurobiological vulnerability to. Gold, De, 1546-1548
blind ratings of mother-infant interaction in home movies of prepsychotic and normal infants. Massie, No, 1371-1374
catatonic dilemma. Brenner, Oc, 1242-1243
defining "schizophreniform psychoses" (ltr to ed). Langfeldt, Jy, 868
eye blink and schizophrenia, tardive dyskinesia or? Stevens, Fe, 223-226
Gilles de la Tourette's syndrome, tardive dyskinesia, and, in adolescent. Caine, Fe, 241-243
high academic achievement in psychotic students. DeFries, Fe, 217-219
hypersensitivity, neuroleptic-induced. Chouinard, No, 1409-1410
hysterical, pseudohomosexuality in male patients with, preliminary report. Miller, Ja, 112-113
imipramine response in deluded depressive patients. Quitkin, Jy, 806-811
impact of neuroleptic chemotherapies on schizophrenic psychoses. Deniker, Au, 923-927
levodopa-induced, kindling phenomenon. Moskovitz, Je, 669-675
mental disturbances during bromocriptine and lergotrile treatment of Parkinson's disease. Serby, Oc, 1227-1229
methadone in schizophrenic rage, case study. Berken, Fe, 248-249
minor physical anomalies in young psychotic children. Campbell, My, 573-575
nonconfusional paranoid, secondary to anticholinergics (ltr to ed). Moore, reply of Klawans, De, 1574
paranoid episodes in manic-depressive psychoses. Fry, Au, 974-976
phencyclidine-induced. Allen, Se, 1081-1084
phenelzine and delusions of parasitosis, case report. Liebowitz, De, 1565-1566
phenelzine-induced. Sheehy, No, 1422-1423
psychobiological research advances in, drug therapy and, in past decade. Bunney, Jy Supp, 8-13
psychoses following therapeutic abortion. Spaulding, Mr, 364-365
psychotic depression and bronchogenic carcinoma. Solomon, Jy, 859-860
schizophrenic, stages of onset of. Docherty, Ap, 420-426
"tardive" (ltr to ed). McCarthy, reply of Tarsy, My, 625-627
two cases of delusions of worm infestation. Munro, Fe, 234-235
Psychosomatic Disorders
adult psychiatrist in medical environment. Moore, Ap, 413-419
amenorrhea and anniversary reaction in woman presenting with chest pain. Miller, Ja, 120-121
drug use by polysurgical patient. DeVaul, Je, 682-685
mind-body dichotomy reified, illustrative case. Schoenberg, Oc, 1224-1226
neurogenic and hysterical seizures in children and adolescents, differential diagnostic and therapeutic considerations. Williams, Ja, 82-86
new method of classification for psychophysiologic disorders. Looney, Mr, 304-308
severe hypertension treated successfully by marital psychotherapy. Summers, Au, 989-990
using phylogenetic mechanisms in classification (ltr to ed). Jonas, Oc, 1250
Psychosurgery
incidence of, in United States, 1971-1973. Donnelly, De, 1476-1480
question of causation (ltr to ed). Brown, reply of Escobar, Je, 760-761

Helps weather
the manic storm
maintenance therapy with
Eskalith® brand of
lithium carbonate
300 mg capsules
Please see other side for a brief summary of prescribing information.

Helps weather the manic storm

In manic-depressive patients with a history of mania, 'Eskalith'

- **prevents or diminishes the intensity of future episodes**
- **can increase the intervals between episodes**
- **helps patients function within normal limits**

maintenance therapy with Eskalith® brand of lithium carbonate

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

WARNING
Lithium toxicity is closely related to serum lithium levels, and can occur at doses close to therapeutic levels. Facilities for prompt and accurate serum lithium determinations should be available before initiating therapy.

Indications: Treatment of manic episodes of manic-depressive illness. Maintenance therapy prevents or diminishes the intensity of subsequent episodes in manic-depressive patients with a history of mania.

Warnings: Lithium should generally not be given to patients with significant renal or cardiovascular disease, severe debilitation or dehydration, sodium depletion, or to patients receiving diuretics.

Lithium therapy has been reported in some cases to be associated with morphologic changes in the kidneys.

Caution patient and family to watch for diarrhea, vomiting, tremor, mild ataxia, drowsiness, or muscular weakness as signs of lithium toxicity, and to discontinue therapy and contact a physician should they occur. Patients receiving combined therapy with lithium and an antipsychotic should be monitored closely for early evidence of neurologic toxicity and treatment discontinued promptly if such signs appear. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery).

Lithium should not be used in pregnancy, especially during the first trimester, unless potential benefits outweigh possible hazards.

Not recommended for children under 12.

Precautions: Lithium tolerance is greater during the acute manic phase and decreases when manic symptoms subside.

Lithium therapy may lead to sodium depletion. Normal diet (including salt) and adequate fluid intake (2500-3000 ml.) must be maintained, at least during initial stabilization period. Protracted sweating or diarrhea can decrease tolerance; in such cases, administer supplemental fluid and salt.

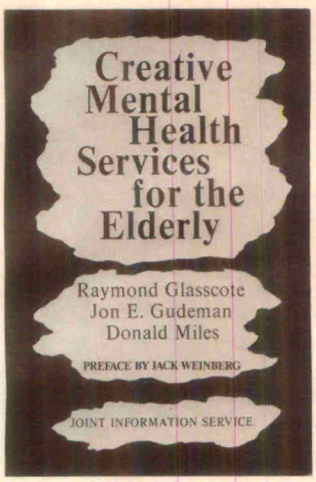
Sweating, diarrhea, and concomitant infection with elevated temperatures may require temporary reduction or cessation of dosage.

Adverse Reactions: Mild to moderate toxic reactions may occur at serum lithium levels from 1.5 to 2.5 mEq./l., and moderate to severe reactions at levels from 2.0 to 2.5 mEq./l. Fine hand tremor, polyuria, and mild thirst may occur during initial therapy and persist. Transient and mild nausea and general discomfort also appear during initial therapy. These effects usually subside with continued treatment or temporary reduction or cessation of dosage. If persistent, discontinue dosage.

Diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination may be early signs of toxicity and may occur at levels below 2.0 mEq./l. At higher levels, ataxia, giddiness, tinnitus, blurred vision, and a large output of dilute urine may be seen. Serum levels above 3.0 mEq./l. may produce a complex clinical picture, involving multiple organs and systems. Serum levels should not exceed 2.0 mEq./l. during acute phase.

The following reactions appear to be related to serum lithium levels, including levels within the therapeutic range: **Neuromuscular**—tremor, muscle hyperirritability (fasciculations, twitching, clonic movements of whole limbs), ataxia, choreo-athetotic movements, hyperactive deep tendon reflex; **Central Nervous System**—blackout spells, epileptiform seizures, slurred speech, dizziness, vertigo, incontinence of urine or feces, somnolence, psychomotor retardation, restlessness, confusion, stupor, coma; **Cardiovascular**—cardiac arrhythmia, hypotension, peripheral circulatory collapse; **Gastrointestinal**—anorexia, nausea, vomiting, diarrhea; **Genitourinary**—albuminuria, oliguria, polyuria, glycosuria; **Dermatologic**—drying and thinning of hair, alopecia, anesthesia of skin, chronic folliculitis, exacerbation of psoriasis, xerosis cutis; **Autonomic**—blurred vision, dry mouth; **Thyroid Abnormalities**—euthyroid goiter and/or hypothyroidism (including myxedema) with lower T_3 and T_4. I^{131} uptake may be elevated; **EEG Changes**—diffuse slowing, widening of the frequency spectrum, potentiation and disorganization of background rhythm; **EKG Changes**—reversible flattening, isoelectricity or inversion of T-waves; **Miscellaneous**—fatigue, lethargy, transient scotomata, dehydration, weight loss, tendency to sleep.

Reactions unrelated to dosage include: transient EEG and EKG changes, leukocytosis, headache, diffuse nontoxic goiter with or without hypothyroidism, transient hyperglycemia, generalized pruritus with or without rash, cutaneous ulcers, albuminuria, worsening of organic brain syndromes, excessive weight gain, edematous swelling of ankles or wrists, thirst or polyuria, sometimes resembling diabetes insipidus, and metallic taste. A single case of a syndrome resembling Raynaud's has been reported.



How Supplied: 300 mg. capsules in bottles of 100.

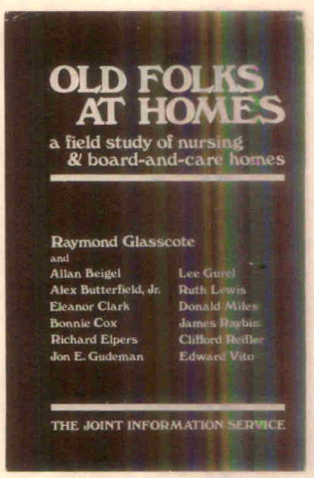
a SmithKline company

The Joint Information Service of the American Psychiatric Association and the Mental Health Association releases Two New Volumes That

Focus on the Elderly



This carefully documented book reports a field study of ten programs, four in America and six in England and Scandinavia, which serve as practical demonstrations of creative mental health services for the elderly. They include:

- a novel "Neighborhood Family" providing vigorous support to elderly residents of several trailer parks
- a high school for the elderly which sends its students abroad for study trips
- a "Human Development Project" that focuses on responding to the psychological needs of the elderly
- a carefully coordinated system of "respite hospitalization," which promotes the health of the elderly while allowing maximum use of hospital beds and family resources
- a "Lucy Booth," patterned after the Peanuts comic strip, which provides easy access to many kinds of services
- and many other innovative, successful approaches.

Each program is subjected to intensive scrutiny. The resulting document becomes a handbook, and, as well, a forum through which some of the world's most experienced practitioners of "the psychiatry of old age" present their views.

Dr. Wilma Donohue, director of the International Center for Social Gerontology, characterizes this volume as "a masterful job of putting everything in relief . . . the guidelines for action are right here."

190 pages. Casebound. Price $8.50.

Concerned about the very bad reputation that nursing homes have received from many quarters in recent years, the Joint Information Service set up a field study to visit a systematically chosen sample of nursing homes, and board-and-care homes as well, to see to what extent the care of and the quality of life for the patients differed from the geriatrics units of state hospitals. Altogether, sixty nursing homes and 31 board-and-care homes in ten locales were visited, in each case by the senior author accompanied by two mental health professionals.

The teams were surpised to learn that care and quality of life in many of the nursing and board-and-care homes they visited were better—sometimes dramatically better—than that in the mental health facilities and often at lower cost.

This unique publication provides an overview of all facilities visited plus vignettes of approximately half. Federal and state rules and regulations are also expertly synthesized into brief and readable style.

148 pages. Casebound. Price $6.50

Artist Leonard Leff uses sculpture to express the painful depression he once experienced. He remembers it as "a lowering of the flame of life. My energies ebbed, my will to live decreased, and I found myself retreating from the activities of life to a more introverted existence."

WHEN DEPRESSION EXPRESSES ITSELF

SINEQUAN®
(DOXEPIN HCl)

ANTIDEPRESSANT EFFECTIVENESS with convenient once-a-day *h.s.* dosage*

150-MG CAPSULE†

Also available in:
100-mg, 75-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE, 10 mg/ml, in 120-ml (4-oz) bottles

*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.

† The 150-mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

ANTIDEPRESSANT EFFECTIVENESS

SINEQUAN®
(DOXEPIN HCl)

150-mg CAPSULE*

*The 150-mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have been reported occasionally. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN (doxepin HCl) in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy. Prescriptions should be written for the smallest feasible amount.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting daily dose of 75 mg is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg/day to 150 mg/day.

In more severely ill patients higher doses may be required with subsequent gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg/day.

The total daily dosage of SINEQUAN (doxepin HCl) may be given on a divided or once-a-day dosage schedule. If the once-a-day schedule is employed the maximum recommended dose is 150 mg/day. This dose may be given at bedtime. **The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.**

Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias and tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (*paralytic ileus*), hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.

B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressive supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions to prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbed. The use of activated charcoal has been recommended, as has been continuous gastric lavage with saline for 24 hours or more. An adequate airway should be established in comatose patients and assisted ventilation used if necessary. EKG monitoring may be required for several days, since relapse after apparent recovery has been reported. Arrhythmias should be treated with the appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CNS symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intravenous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine is rapidly metabolized, the dosage should be repeated as required. Convulsions may respond to standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depression. Dialysis and forced diuresis generally are not of value in the management of overdosage due to high tissue and protein binding of SINEQUAN.

Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to: 10 mg, 75 mg, and 100 mg doxepin: bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). 25 mg and 50 mg doxepin: bottles of 100, 1000, 5000, and unit-dose packages of 100 (10 x 10's). 150 mg doxepin: bottles of 50, 500, and unit-dose packages of 100 (10 x 10's). SINEQUAN Oral Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 mg doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted with approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number of carbonated beverages. For those patients requiring antidepressant therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water, but not with grape juice. Preparation and storage of bulk dilutions is not recommended.

More detailed professional information available on request.

VERY OFTEN
THE DIFFERENCE IN TRANQUILIZERS
IS IN THE PATIENT'S MIND.

Sometimes patients for whom you are prescribing a minor tranquilizer as an adjunct to psychotherapy present attitudes or feelings that may influence your choice of an anxiolytic. For many of these patients AZENE® (clorazepate monopotassium) CIV is a logical choice.

THE PATIENT WHO IS FAMILIAR WITH ONE BRAND OF MEDICATION

AZENE® gives you an option benzodiazepine probably unfamiliar to your patients.

THE PATIENT REENTERING THERAPY FOR WHOM YOU MAY PREFER A NEW MEDICATION

AZENE® is one of the newer benzodiazepines and is clinically effective.

THE PATIENT FOR WHOM THE OPTION OF *h.s.* DOSAGE MIGHT BE BENEFICIAL

AZENE® provides the opportunity for dosage flexibility. Recommended starting dose is 6.5 mg *t.i.d.* For patients currently receiving *t.i.d.* dosing, consider switching to an *h.s.* schedule. For patients who might benefit from a lower daily dosage schedule, consider a starting daily dose of 13 mg *h.s.*

THE PATIENT WHO MUST MAINTAIN A NORMAL WORK SCHEDULE*

AZENE® controls anxiety yet avoids excessive sedation in most patients. If sedation is a problem, the flexibility of the nighttime dosing may reduce or alleviate this problem. AZENE® is thus a logical choice for patients who want relief of anxiety without troublesome sedation.

*Of course, patients should be advised against engaging in hazardous activities that require mental alertness.

Please see brief summary of prescribing information on the following page.

BRIEF SUMMARY OF PRESCRIBING INFORMATION

CONTRAINDICATIONS AZENE® is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS AZENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on AZENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since AZENE (clorazepate monopotassium) has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, AZENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepates. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Tolerance developed within 3 to 9 days in dogs. Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. AZENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

AZENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Periodic blood counts and liver function tests are advisable for patients on AZENE for prolonged periods. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In elderly or debilitated patients, the initial dose should be small, and increments should be made gradually, in accordance with the response of the patient, to preclude ataxia or excessive sedation.

ADVERSE REACTIONS The side effect most frequently reported with the use of benzodiazepines is drowsiness. Less commonly reported side effects are: dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects include insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and of decrease in hematocrit.

Decrease in systolic blood pressure has been observed with clorazepates.

DRUG INTERACTIONS If AZENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that clorazepates prolong the sleeping time after hexobarbital or after ethyl alcohol, increase the inhibitory effects of chlorpromazine, but do not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If AZENE is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

HOW SUPPLIED AZENE (clorazepate monopotassium) is supplied as capsules in three dosage strengths: 3.25 mg capsules (light tan-colored) in bottles of 100 and 500. 6.5 mg capsules (orange-colored) in bottles of 100 and 500. 13 mg capsules (blue-colored) in bottles of 100. 6092-3 BS

JESSE JONES BOX CORP. (Since 1843)
Department JP9—Philadelphia 41, Pa. 19141

The American Psychiatric Association announces publication of two volumes reporting the Conference on Education of Psychiatrists

held at Lake of the Ozarks, Missouri, June 9-15, 1975. Organized by the A.P.A. in cooperation with the American Academy of Child Psychiatry, the American Association of Chairmen of Departments of Psychiatry, and the American Association of Directors of Psychiatric Residency Training.

1. PSYCHIATRIC EDUCATION: PROLOGUE TO THE 1980's, Library Bound, 544 pages, $15.00.

This is a substantive, highly readable, report of the Conference, written by Anne H. Rosenfeld with an Editorial Board comprising: Ewald W. Busse, M.D., Chairperson of the Conference, Walter E. Barton, M.D., Bernard Holland, M.D., Donna Norris, M.D., Melvin Sabshin, M.D., Jeanne Spurlock, M.D., and Robert L. Robinson, M.A. (Staff Consultant).

The volume contains ten chapters covering the topical structure of the Conference: Goals and Values; Competence, Evaluation, and Quality Control; The Resident; Faculty; Educational Methods: Means in the Service of Ends; The Program Environment; Research; The Economics of Residency Training; Psychiatry in Its Social Context; and Retrospect and Prospect. It also contains nine appendices describing the organization of the Conference and its participants, together with selected model programs and related informational materials of value.

2. THE WORKING PAPERS OF THE 1975 CONFERENCE ON EDUCATION OF PSYCHIATRISTS Paper bound, 432 pages, $12.50.

Sixty two leading psychiatric educators served on seven preparatory commissions, one for each of seven topic areas, and prepared advance working papers as a basis for Conference deliberations. The topics and Commission Chairpersons were: Social Issues and Needs (James N. Sussex, M.D.); Goals and Objectives (Morton F. Reiser, M.D.); The Resident (David R. Hawkins, M.D.); Content, Methodology, Faculty and Environment (Milton Greenblatt, M.D.); Research (Daniel X. Freedman, M.D.); Economics (Herzl Spiro, M.D.); Evaluation and Quality Control (Eric Pfeiffer, M.D.). The Chairpersons, together with the Conference Chairperson, served as the Editorial Board for this volume.

Papers commenting on the reports of the commissions, published here for the first time, were presented at the Conference by Melvin Sabshin, M.D., Eugene B. Brody, M.D., Jeanne Spurlock, M.D., Jack R. Ewalt, M.D., Robert J. Stoller, M.D., James R. Comer, M.D., and Bernard Holland, M.D.

The antidepressant
remain alert and

- relieves depression without causing problem daytime
- insomnia of depression begins to improve within a week
- PAMELOR therapy is well tolerated

Indications: For relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Hypersensitivity. Should not be given concomitantly with MAO inhibitors or within 2 weeks of the use of this drug since hyperpyretic crises, severe convulsions, and fatalities have occurred when similar tricyclic antidepressants were used in such combinations. Cross-sensitivity with other dibenzazepines is a possibility. Contraindicated during acute recovery period after myocardial infarction.

Warnings: Use with caution in patients with cardiovascular disease because of tendency to produce sinus tachycardia and prolong conduction time. Myocardial infarction, arrhythmia, and strokes have occurred. May block antihypertensive action of guanethidine and similar agents. Because of anticholinergic activity, use cautiously in patients with glaucoma or a history of urinary retention. Patients with a history of seizures should be followed closely because the drug is known to lower the convulsive threshold. Great care is required for hyperthyroid patients and those taking thyroid medication because of possible development of cardiac arrhythmia. Caution patients about possibility of impaired mental and/or physical ability to operate a motor vehicle or dangerous machinery. Response to alcoholic beverages may be exaggerated and may lead to suicidal attempts. Safe use during pregnancy, lactation, and women of childbearing potential has not been established and the drug should not be given unless clinical situation warrants potential risk. Not recommended for use in children.

Precautions: Psychotic symptoms may be exacerbated in schizophrenic patients. Increased anxiety and agitation may occur in overactive or agitated patients. Manic-depressive patients may experience shift to manic phase. Hostility may be aroused. Concomitant administration of reserpine may produce a "stimulating" effect. Watch for possible epileptiform seizures during treatment. Use cautiously with anticholinergic or sympathomimetic drugs. Concurrent electroconvulsive therapy may increase hazards associated with nortriptyline HCl. When possible, discontinue drug several days prior to surgery. Potentially suicidal patients require supervision and protective measures during therapy. Prescriptions should be limited to the least possible quantity. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: The pharmacologic similarities among the tricyclic antidepressant drugs require that each of the following reactions be considered when nortriptyline is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia, panic, nightmares; hypomania; exacerbation of psychosis.

Neurologic: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alteration in EEG patterns; tinnitus.

Anticholinergic: Dry mouth and rarely, associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with other tricyclic drugs.

Hematologic: Bone-marrow depression, including agranulocytosis; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black-tongue.

Endocrine: Gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness, fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though these are not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Dosage and Administration: *Usual adult dose* – 25 mg. three four times daily; dosage should begin at a low level and increas required. As an alternate regimen, the total daily dosage ma given once-a-day. *Elderly and Adolescent* - 30 to 50 mg. per divided doses, or the total dosage may be given once-a-d above 100 mg. per day and use in children are not recom a patient develops minor side effects, the dosage sh duced. The drug should be discontinued promptly if a of a serious nature or allergic manifestations occur.

How Supplied: Capsules 10 mg. and 25 mg.; solution

ptyline HCl) NF

25mg. Capsules.

Patients remain alert.

Most depressed patients must function effectively in their daily activities, on the job or at home. For these patients, PAMELOR capsules may be an appropriate therapeutic choice. PAMELOR relieves depression, yet rarely causes daytime drowsiness. As with all antidepressants, however, patients should be cautioned against driving or operating hazardous machinery.

Insomnia of depression begins to improve within a week.

PAMELOR capsules are effective for relieving insomnia, a cardinal symptom of depressive illness. Patients begin to sleep better within the first week of therapy. The full therapeutic effect of PAMELOR is usually observed by the second week.

PAMELOR therapy is well tolerated.

In 90 studies, a total of 818 patients were treated with PAMELOR capsules. Of the patients who improved completely or markedly, over half (54%) had no side effects. Those who experienced side effects most commonly complained of dry mouth.

MANUAL OF PSYCHIATRIC PEER REVIEW

by the Peer Review Committee of the American Psychiatric Association, Donald G. Langsley, M.D., Chairperson in cooperation with the Joint Task Force on Diagnostic Criteria for Analyzability of the American Psychoanalytic Association, William Offenkrantz, M.D., Chairperson, and the Peer Review Committee of the American Academy of Child Psychiatry. Larry B. Silver, M.D., Chairperson.

"This Manual provides a set of guidelines for district branches of APA and their peer review committees which should be adapted and modified in terms of local criteria, standards, and practices. The guidelines are not intended to be hard and fast rules. They are screening criteria, and not regulations to control practice. They are so designed that they can be utilized by non-physicians to identify those cases that can profitably be reviewed by psychiatrists serving on peer review committees. This document should be viewed as transitional, subject to revision as experience is gained, and continually updated in response to advances in psychiatric knowledge and changes in patterns of practice. . . . The application of these standards, and refinement through experience must rest with the peer review committees of district branches. . . . It should help them to move ahead in the development of a peer review for American psychiatry."

Robert W. Gibson, M.D.
President

Part I titled PSYCHIATRIC PEER REVIEW contains sections on Basic Relationships and Responsibilities, Appointment of Peer Review Committees, Funding, Operations and Procedures, Medical Care Evaluation Studies, Appeals Processes, Special Problems, Confidentiality, Educational Aspects, Medical Ethics, Advocacy, Interdisciplinary Aspects, with Appendices on Model Screening Format for Inpatient Treatment for Alcoholism, Model Screening Format for Outpatient Treatment, Sample Form for Requesting Extension of Office Treatment, Claims Review Guidelines Suggestions, APA Position Papers on Peer Review, Bibliography.

Part II titled PSYCHOANALYTIC PEER REVIEW has sections on Steps in Peer Review for Psychoanalysis, Guidelines for Model Criteria Sets, Pilot Application of Guidelines for Model Criteria Sets, Sample Peer Review Form, Sample data from Pilot Applications of Guidelines, and Glossary of Terms Used.

Part III titled PEER REVIEW AND CHILD PSYCHIATRY contains sections of Special Considerations, Legal Rights of Children, Issue of Confidentiality, Conclusions, References, and Appendices on Model Screen Criteria Format for Intermediate Care, for Acute Care in a Short Stay Facilities, and for Partial Hospitalization, Outpatient Diagnostic Evaluation Procedures, and Outpatient Treatment for Children and Adolescents.

Psychiatric Associateships at National Institute of Mental Health

The National Institute of Mental Health Associate Program at the National Institutes of Health is offering two or three year Associateships for intensive training in virtually all areas of clinical and basic psychobiological research. The program is currently approved for a third year of residency training. Applicants should be in their last year of training or should have completed training by the start of the appointment and should be U.S. citizens or eligible for naturalization within four years of the expected appointment date. Applications are due by January 15, 1979 for appointments which begin July 1980.

Excellent facilities are available at The Clinical Center on the 306-acre NIH campus in Bethesda, Maryland, and at nearby St. Elizabeth's Hospital in Washington, D.C. Clinical Associates are assigned clinical responsibility in caring for patients who are admitted for both therapeutic and research purposes. Research Associates engage in laboratory research under the preceptorship of one of the senior staff and may participate in tutorial seminars and other teaching programs.

A competitive salary is available for candidates qualifying for appointment in the Commissioned Corps, United States Public Health Service. A portion of the salary is tax exempt. Moving and travel expenses are paid and health care is free.

An NIH Associate Training Program

An Equal Opportunity Employer

Psychiatry Chairman

Lutheran General, an 800 bed teaching hospital, is seeking a Chairman for the Division of Psychiatry. The Division encompasses approximately 200 in-patient beds divided between general psychiatric care, alcoholism treatment and medical psychiatric care along with an active outpatient service and a Day Hospital.

The Chairman's responsibilities include accountability for the medical care administered to psychiatric and alcoholism patients, coordination of undergraduate medical education, planning and development of residency training in Psychiatry and the administrative aspects of managing a large clinical area. Requirements for this position include Board Certification in Psychiatry, experience in direct patient care, prior teaching experience and demonstrated administrative and management skills. Eligibility for faculty appointment is essential.

Lutheran General Hospital is located in an affluent northwest suburb of Chicago and offers many educational and cultural opportunities. The hospital is affiliated with the Abraham Lincoln College of Medicine of the University of Illinois and currently has residencies in Internal Medicine, Emergency Medicine, Family Practice, Pediatrics, Surgery, Pathology and Radiology. Lutheran General is committed to a multidisciplinary approach to treatment, as expressed in our unique philosphy of patient care. We offer a very competitive compensation package. For consideration please submit curriculum vita to:

If you won't read these 7 signals of cancer...

You probably have the 8th.

1. Change in bowel or bladder habits.
2. A sore that does not heal.
3. Unusual bleeding or discharge.
4. Thickening or lump in breast or elsewhere.
5. Indigestion or difficulty in swallowing.
6. Obvious change in wart or mole.
7. Nagging cough or hoarseness.

8. A fear of cancer that can prevent you from detecting cancer at an early stage. A stage when it is highly curable. Everyone's afraid of cancer, but don't let it scare you to death.

Tranxene® (CLORAZEPATE DIPOTASSIUM) 4306CB

CAPSULES,
SINGLE DOSE TABLETS
Brief Summary

ACTIONS — Pharmacologically, clorazepate dipotassium has the characteristics of the benzodiazepines. It has depressant effects on the central nervous system. The primary metabolite, nordiazepam, quickly appears in the blood stream. The serum half-life is about 2 days. The drug is metabolized in the liver and excreted primarily in the urine. (See CLINICAL PHARMACOLOGY section.)

INDICATIONS — TRANXENE is indicated for the symptomatic relief of anxiety associated with anxiety neurosis, in other psychoneuroses in which anxiety symptoms are prominent features, and as an adjunct in disease states in which anxiety is manifested.

TRANXENE is indicated for the symptomatic relief of acute alcohol withdrawal.

The effectiveness of TRANXENE in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should reassess periodically the usefulness of the drug for the individual patient.

CONTRAINDICATIONS — TRANXENE is contraindicated in patients with a known hypersensitivity to the drug, and in those with acute narrow angle glaucoma.

WARNINGS — TRANXENE is not recommended for use in depressive neuroses or in psychotic reactions.

Patients on TRANXENE should be cautioned against engaging in hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles.

Since TRANXENE has a central nervous system depressant effect, patients should be advised against the simultaneous use of other CNS-depressant drugs, and cautioned that the effects of alcohol may be increased.

Because of the lack of sufficient clinical experience, TRANXENE is not recommended for use in patients less than 18 years of age.

Physical and Psychological Dependence:

Withdrawal symptoms (similar in character to those noted with barbiturates and alcohol) have occurred following abrupt discontinuance of clorazepate. Symptoms of nervousness, insomnia, irritability, diarrhea, muscle aches and memory impairment have followed abrupt withdrawal after long-term use of high dosage.

Caution should be observed in patients who are considered to have a psychological potential for drug dependence.

Evidence of drug dependence has been observed in dogs and rabbits which was characterized by convulsive seizures when the drug was abruptly withdrawn or the dose was reduced; the syndrome in dogs could be abolished by administration of clorazepate.

Usage in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. TRANXENE, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Usage during Lactation:

TRANXENE should not be given to nursing mothers since it has been reported that nordiazepam is excreted in human breast milk.

PRECAUTIONS — In those patients in which a degree of depression accompanies the anxiety, suicidal tendencies may be present and protective measures may be required. The least amount of drug that is feasible should be available to the patient.

Patients on TRANXENE for prolonged periods should have blood counts and liver function tests periodically. The usual precautions in treating patients with impaired renal or hepatic function should also be observed.

In debilitated patients, the initial dose should be small, and increments made gradually, in accordance with the response of the patient, to avoid ataxia or excessive sedation.

ADVERSE REACTIONS — The side effect most frequently reported was drowsiness commonly reported (in descending order of occurrence) dizziness, various gastrointestinal complaints, nervousness, blurred vision, dry mouth, headache, and mental confusion. Other side effects include insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression and slurred speech.

There have been reports of abnormal liver and kidney function tests and decrease in hematocrit.

Decrease in systolic blood pressure has been observed.

DOSAGE AND ADMINISTRATION

For the symptomatic relief of anxiety:

TRANXENE is administered orally. The capsules may be given in divided doses. The usual daily dose is 30 mg. The dose should be adjusted gradually within the range of 15 to 60 mg. daily in accordance with the response of the patient. In elderly or debilitated patients it is advisable to initiate treatment at a daily dose of 7.5 to 15 mg.

TRANXENE capsules may also be administered as a single dose daily at bedtime; the recommended initial dose is 15 mg. After the initial dose, the response of the patient may require adjustment of subsequent dosage. Lower doses may be indicated in the elderly patient. Drowsiness may occur at the initiation of treatment and with dosage increment.

TRANXENE-SD tablets (22.5 mg.) may be administered as a single dose every 24 hours. This tablet is intended as an alternate dosage form for the convenience of patients stabilized on a dose of 7.5 mg. capsules three times a day. TRANXENE-SD tablets should not be used to initiate therapy.

TRANXENE-SD HALF STRENGTH tablets (11.25 mg.) may be administered as a single dose every 24 hours.

For the symptomatic relief of acute alcohol withdrawal:

Recommended schedule: 1st 24 hours, 30 mg. TRANXENE initially, followed by 30 to 60 mg. in divided doses; 2nd 24 hours, 45 to 90 mg. in divided doses; 3rd 24 hours, 22.5 to 45 mg. in divided doses; 4th day, 15 to 30 mg. in divided doses. Thereafter gradually reduce to 7.5 to 15 mg. daily, and discontinue as soon as condition is stable. Maximum daily dose is 90 mg. Avoid excessive reductions in total drug on successive days.

DRUG INTERACTIONS — If TRANXENE is to be combined with other drugs acting on the central nervous system, careful consideration should be given to the pharmacology of the agents to be employed. Animal experience indicates that TRANXENE prolongs the sleeping time after hexobarbital or after ethyl alcohol, increases the inhibitory effects of chlorpromazine, but does not exhibit monoamine oxidase inhibition. Clinical studies have shown increased sedation with concurrent hypnotic medications. The actions of the benzodiazepines may be potentiated by barbiturates, narcotics, phenothiazines, monoamine oxidase inhibitors or other antidepressants.

If TRANXENE is used to treat anxiety associated with somatic disease states, careful attention must be paid to possible drug interaction with concomitant medication.

MANAGEMENT OF OVERDOSAGE — Overdosage is usually manifested by varying degrees of CNS depression ranging from slight sedation to coma. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken.

There are no specific antidotes for the benzodiazepines. The treatment of overdosage should consist of the general measures employed in the management of overdosage of any CNS depressant. Gastric evacuation either by the induction of emesis, lavage, or both, should be performed immediately. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated. Hypotension, though rarely reported, may occur with large overdoses. In such cases the use of agents such as Levophed® (levarterenol) or Aramine® (metaraminol) should be considered.

While reports indicate that individuals have survived overdoses of TRANXENE (clorazepate dipotassium) as high as 450 to 675 mg., these doses are not necessarily an accurate indication of the amount of drug absorbed since the time interval between ingestion and the institution of treatment was not always known. Sedation in varying degrees was the most common physiological manifestation of TRANXENE overdosage. Deep coma when it occurred was usually associated with the ingestion of other drugs in addition to TRANXENE.

CLINICAL PHARMACOLOGY — Studies in healthy men have shown that TRANXENE has depressant effects on the central nervous system. Prolonged administration of single daily doses as high as 120 mg. was without toxic effects. Abrupt cessation of high doses was followed in some patients by nervousness, insomnia, irritability, diarrhea, muscle aches, or memory impairment.

Absorption — Excretion:

After oral administration of TRANXENE, there is essentially no circulating parent drug. Nordiazepam, its primary metabolite, quickly appears in the blood stream. In 2 volunteers given 15 mg. (50 μC) of ^{14}C-TRANXENE, about 80% was recovered in the urine and feces within 10 days. Excretion was primarily in the urine with about 1% excreted per day on day 10.

HOW SUPPLIED — TRANXENE (clorazepate dipotassium) is supplied as capsules in three dosage strengths:

3.75 mg. capsules (gray with white cap) in bottles of 100 (NDC 0074-3417-13) and 500 (NDC 0074-3417-53). Also available in ABBO-PAC® unit dose packages of 100 capsules (NDC 0074-3417-11).

7.5 mg. capsules (gray with maroon cap) in bottles of 30 (NDC 0074-3418-30), 100 (NDC 0074-3418-13) and 500 (NDC 0074-3418-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3418-11).

15 mg. capsules (all gray) in bottles of 100 (NDC 0074-3419-13) and 500 (NDC 0074-3419-53). Also available in ABBO-PAC unit dose packages of 100 capsules (NDC 0074-3419-11).

TRANXENE-SD single dose tablets are supplied in two dosage strengths:

TRANXENE-SD 22.5 mg. tablets (tan-colored) in bottles of 100 (NDC 0074-2997-13).

TRANXENE-SD HALF STRENGTH 11.25 mg. tablets (blue-colored) in bottles of 30 (NDC 0074-2699-30) and 100 (NDC 0074-2699-13).

8103277

Not drowsy by day, yet anxiety controlled

Troublesome drowsiness uncommon. Tranxene lets you manage anxiety in most patients without problem sedation. Any initial drowsiness is usually transient. By avoiding excessive sedation, Tranxene helps you calm patients without compromising their capacities.*

CAPSULES: 3.75, 7.5, 15 mg.
TABLETS: 11.25, 22.5 mg.
